Quantum Maps: Completely Positive Maps - Part 02

So, what we have proved in the second choi theorem is that if you have a completely positive map ω , the only condition we have is ω is a completely positive map. Then we can find at least one set of operators K_n such that the map, the action of the map ω on operator ρ can be written as $\sum_n K_n \rho K_n^\dagger$. And this we achieved by assuming or by finding a very special operator E such that the ij -th block in that E is the ij -th matrix. So, because ij matrix is the basis for an arbitrary operator, if we can find the action of the map ω on ij , we can find the action of ω on any arbitrary operator ρ . This is what we did and we found the operator sum representation or Kraus operator representation of the ω .

(Refer slide time: 00:19)

The image shows a chalkboard with handwritten mathematical equations. The equations are:

$$= \sum_{ij} \rho_{ij} \sum_n K_n |i\rangle\langle j| K_n^\dagger$$
$$= \sum_n K_n \left(\underbrace{\sum_{ij} \rho_{ij} |i\rangle\langle j|}_\rho \right) K_n^\dagger$$
$$\Rightarrow \boxed{\omega(\rho) = \sum_n K_n \rho K_n^\dagger} \quad \square$$

In the bottom right corner of the chalkboard, there is a small inset video of a man speaking. The NPTEL logo is visible in the top right corner of the chalkboard area.

So, what the first theorem of choi is that operator sum representation implies completely positive map. And second one says that completely positive map implies operator sum representation. So, it means all the positive map can be written in the operator sum representation and operator sum representation can be written in terms of the positive map, is a completely positive map. So, with this, we are done with the proof of the choi's

theorem. Just to connect it with what we have already done, for positive operator, positive maps also, we found that H can be related to the sum over n λ_n , K_n outer product k_n .

(Refer slide time: 3:04)

1. OSR \Rightarrow CP
 2. CP \Rightarrow OSR

\rightarrow tve map $H = \sum_n \lambda_n |k_n\rangle\langle k_n|$
 $\Omega(A) = \sum_n \lambda_n |k_n\rangle A \langle k_n|$
 $\lambda_n \neq 0$

\rightarrow CP $\Omega(A) = \sum_n \lambda_n |k_n\rangle A \langle k_n|$
 $\lambda_n \geq 0$

Okay, or the action of omega or a matrix A could be written as sum over n , λ_n , K_n , A , K_n dagger, but λ_n need not be all positive. Need not be all positive semi definite. Okay, but for completely positive map, omega of A can be written as sum over n λ_n K_n a K_n dagger where λ_n are all positive this is the difference between positive map and completely positive map but this condition is not enough for a positivity of the map, because this condition only assumes, this condition can be only derived from the hermiticity condition not the positive positivity condition of the map but all the positive maps are Hermitian also so this condition is valid for, this condition is necessary but not sufficient for all the positive maps but this is necessary and sufficient condition for the completely positive map, so in that way there is a relation between positive maps and completely positive maps. If we want to see then there is a set of all the maps.

It's a graphical representation, so all the maps we have, then there is a subset of these maps which are Hermitian maps then there is a smaller subset of it which are positive maps and there is a smaller subset for the smaller subset inside it which are CP maps. So, all the map, the Hermitian map, then positive map and all the CP maps. This small subset of maps is what represents the physical states on a quantum system. Only these maps, not all the other maps. So far, we have been only saying that completely positive maps represent physical processes and all the physical processes can be represented by completely positive maps.

(Refer slide time: 4:10)

But in this lecture, we will establish that connection and give a formal proof of this statement. But before that, we need to understand what we call a physical process. In quantum mechanics, only unitary transformations are valid transformation. It means only unitary transformations can transform one state to another state. So, as far as quantum mechanics of an isolated quantum system is concerned, only unitary processes are physical processes.

If we assume that there is nothing beyond our existing universe, we see if there is nothing outside that universe that you know then that entire universe forms an isolated quantum system it means the dynamics of the whole universe will be a unitary transformation. So, if we are interested in the dynamics of a system as then we can think of it S plus the entire universe or we call it ancilla, some assisting universe or assisting quantum system. So, the total Hilbert space is H_A tensor H_S . So, any process which can be defined any process on Hilbert space H_S if we can define it as a unitary process on H_A tensor H_S and the reduced dynamics of that only on the system, then we will call it a physical process. What I mean is if we have a dynamic or a process which takes ρ to ρ prime where ρ belongs to the set of operators acting on H_S then ρ is a state of system S and the process takes ρ to ρ prime.

(Refer slide time: 6:29)

If we can write it as a unitary process on a state ρ_A of ancilla tensor ρ_S or ρ of the system U^\dagger and then traced over ancilla, if the dynamics or the process we are interested in the physical process, if that can be represented by the unitary action of on the system and ancilla and tracing out the ancilla, then we will call it a physical process. So, in other words, if the desired process can be achieved by a unit transformation on an enlarged system, then this process must be physical. So, whenever we say physical process now onward, this is what we will mean. Now the point is from the Choi's theorem, we know if ω is a completely positive map then action of ω on ρ can always be written as $\sum_i K_i \rho K_i^\dagger$, so this is the crux of the two Choi's theorem theorem and if we want the trace of the achieved state to be preserved so ω of the trace of ω of ρ to be one for all the ρ 's then it means $\sum_i \text{trace of } K_i \rho K_i^\dagger$ must be equal to one. One equality I would like you to verify that if we have trace of product of three matrices A, B and C, then it is same as trace of C, A, B. This is the cyclic property of the trace.

(Refer slide time: 8:52)

$(\omega) \rho \rightarrow \rho' = \text{Tr}_A(U(\rho_A \otimes \rho)U^\dagger) \rightarrow \text{Physical Process}$
 $\mathcal{S} \rightarrow \mathcal{C}P$
 $\omega(\rho) = \sum_i K_i \rho K_i^\dagger$
 $\text{Tr}(\omega(\rho)) = 1 = \sum_i \text{Tr}(K_i \rho K_i^\dagger) = 1$
 $\rightarrow \text{Tr}(ABC) = \text{Tr}(CAB)$
 $\rightarrow \text{Tr}(K_i \rho K_i^\dagger) = \text{Tr}(K_i^\dagger K_i \rho)$

We can use this property. Then we get trace of $K_i \rho K_i^\dagger$ to be equal to trace of $K_i^\dagger K_i \rho$. Hence, trace of $\omega \rho$ becomes $\sum_i \text{trace of } K_i^\dagger K_i \rho$ to be equal to 1 for all the states ρ such that trace of ρ is 1. This is true for all the states ρ . It means that $\sum_i K_i^\dagger K_i$ must be identity.

(Refer slide time: 10:19)

$$\text{Tr}[\Omega(I)] = \sum_i \text{Tr}[K_i^\dagger K_i \rho] = 1 \quad \forall \rho$$

$$\Rightarrow \sum_i K_i^\dagger K_i = I$$

$$\Omega(\rho) = \sum_i K_i \rho K_i^\dagger, \quad \sum_i K_i^\dagger K_i = I$$

$$\mathcal{H}_A, \rho_A, U$$

$$\rho_{AS} = \rho_A \otimes \rho$$

So, this condition over the operators K_i is the condition for trace preserving nature. So, omega of rho for a completely positive and trace preserving map can be written as sum over i $K_i \rho K_i^\dagger$ and $K_i^\dagger K_i$ sum over i is identity. Now, we have to find a unitary process. We have to, in order to show that this completely positive map can be achieved, it represents a physical process, then we need to find an ancilla, \mathcal{H}_A , the Hilbert space of the ancilla and the initial state ρ_A of the ancilla, a unitary operator U such that the action of U on $\rho_A \otimes \rho$ and then tracing out the ancilla gives us a completely positive map. The initial state let us say ρ_{AS} is $\rho_A \otimes \rho$ where ρ is the state we are interested in, after that we do the unitary transformation then we get $\tilde{\rho}_{AS}$ to be $U \rho_A \otimes \rho U^\dagger$.

(Refer slide time: 13:05)

Unitary transformation

$$\tilde{\rho}_{AS} = U(\rho_A \otimes \rho)U^\dagger$$

$$\text{Tr}_A(\tilde{\rho}_{AS}) = \tilde{\rho} = \text{Tr}_A[U(\rho_A \otimes \rho)U^\dagger]$$

let $\rho_A = |4\rangle\langle 4|$

$$\text{Tr}[Z] = \sum_n \langle n|Z|n\rangle; \{|n\rangle\} \text{ ONB}$$

$$\rightarrow \tilde{\rho} = \sum_n \langle n| \otimes \langle 1| U(|4\rangle\langle 4| \otimes \rho) U^\dagger (|n\rangle \otimes |2\rangle)$$

$$K_n = \langle n| \otimes \langle 1| U(|4\rangle \otimes |1\rangle)$$

$$\rightarrow \tilde{\rho} = \sum_n K_n \rho K_n^\dagger \quad \text{Operator Sum Rule CP}$$

And then we trace over ancilla, we get $\tilde{\rho}$, which is trace over ancilla $U \rho_A \otimes \rho U^\dagger$. Let us assume that ρ_A is a pure state. And let us remember the trace over operators Z is sum over n $\langle n|Z|n\rangle$ where n is the orthonormal basis. So we use

these two and we get trace over, we get rho tilde to be sum over n, we are getting trace over only over one subsystem, so n tensor identity on the other, U rho A is psi tensor rho U dagger n tensor identity. So, this is our rho tilde. Now, let us define, now let us define K_n , which is n tensor identity, U psi tensor identity. So, we are projecting the ancilla space on the state n on the left side and psi on the right side.

(Refer slide time: 14:30)

$$\Omega(\rho) = \sum_i K_i \rho K_i^\dagger, U, |\psi\rangle$$

$$K_n = \langle n | \otimes U (|\psi\rangle \otimes |0\rangle)$$

$$|\psi\rangle = |0\rangle = \begin{bmatrix} 1 \\ 0 \\ 0 \\ \vdots \end{bmatrix} \quad |n\rangle = \begin{bmatrix} 0 \\ \vdots \\ 1 \\ \vdots \end{bmatrix} \rightarrow n^{\text{th}}$$

The U is an operator acting on ancilla and system. And we are projecting it in the n size space so that the leftover operator is the operator acting on only the system so K_n are the operators acting on the system. So, with this definition we can see that rho tilde is sum over n $K_n \rho K_n^\dagger$. So in that way, every physical process represented by the unitary operator U and the ancilla states psi, we can always get operator sum representation. Hence, it is a completely positive map. But next question we want to answer is given a completely positive map Ω , whose action is represented by sum over i, $K_i \rho K_i^\dagger$, can we find a unitary operator U and the state psi corresponding to this set of operators K_i 's, okay. Now, you see K_i is or K_n is n, which let us take to be the computational basis, U tensor identity U and psi tensor identity. For simplicity, let us say psi is the zeroth computational state, so it means it is one zero zero zero zero and so on and n is also a computational basis so it will be zero zero zero one zero zero zero where this is the nth position. And U can be written as sum over ij, i outer product j tensor small u_{ij} , okay. So, it means we can write it as $u_{11} u_{12} u_{13} u_{21} u_{22}$ and so on, where u_{ij} are the operators acting on the Hilbert space of the system.

(Refer slide time: 15:25)

$$U = \sum_{i,j} |i\rangle\langle j| \otimes U_{ij}$$

$$= \begin{bmatrix} u_{11} & u_{12} & u_{13} & \dots \\ u_{21} & u_{22} & & \\ & & & \\ & & & \end{bmatrix}$$

$u_{ij} \in \mathbb{C}(\mathbb{R})$

$$\langle n| \otimes U |0\rangle \otimes \rho = U_{n0} = K_n$$

So, it means n tensor identity U 0 tensor identity is U_{n0} and which is K_n . So, it means u_{11} , sorry it is 0 . This is one, the counting is from zero not from one, so u_{10} u_{20} u_{30} and so on are k_1 k_2 k_3 and so on. So, it means the unitary, if we choose unitary to be of the form k_0 k_1 counting is from 0 , so let me make this also 0 , k_2 and k_n where n is there where n projectors or n k operators. From here we can see that the first column of operators is occupied by the Kraus operators k_i 's which represents the completely positive map ω and you know and U must be a unitary operator so the rest of the matrix R is chosen in such a way that the U is unitary and a square matrix. And this R is completely arbitrary. We can choose anything as long as U is unitary. This with the initial state of the ancilla to be computational state 0 , we have found a physical process corresponding to the completely positive ω given by the Kraus operators, represented by the Kraus operators k 's. So, in that way, we have shown that completely physical process given by unitary operator U and initial state of the ancilla ψ . this corresponds to a set of Kraus operators k_n . In a set of Kraus operators k_n , we can always find a unitary U acting on ancilla and system together jointly and the state of the ancilla to be ψ .

(Refer slide time: 18:00)

$$U = \begin{bmatrix} k_0 \\ k_1 \\ k_2 \\ \vdots \\ k_n \end{bmatrix} R ; |0\rangle$$

$$\rightarrow U, |\psi\rangle \rightarrow \{k_n\}$$

$$\{k_n\} \rightarrow U, |\psi\rangle$$

Let me repeat. What we have shown is for a given unitary acting on ancilla and system and the initial state of ancilla, this correspond to a completely positive map CP given by the Kraus operator k_n . Alternatively, if we are given a set of Kraus operator, we can always find a unitary U acting on system and ancilla and an initial state of the system. So, in that way, completely positive maps represent physical processes and physical processes represent completely positive maps. And hence, we have established the relation between the completely positive maps and physical processes.

There are some properties of Kraus operators and completely positive maps, which we need to keep in mind. First of all, for a map $\rho \rightarrow \sum_n K_n \rho K_n^\dagger$, the choice of K_n is not unique. So, there exist R_m such that $\sum_m R_m \rho R_m^\dagger$, sum over m is also omega of ρ . To prove this thing, let us say R_m is chosen in such a way it is a $W_{nm} K_n$. Okay, so and sum over n then $\sum_m R_m \rho R_m^\dagger$, sum over m can be written as sum over n , n' and m $W_{nm} K_n \rho W_{n'm}^\dagger K_{n'}^\dagger$.

(Refer slide time: 18:56)

$\rho \rightarrow \sum_n K_n \rho K_n^\dagger$
 $\{K_n\}$ Not unique.
 $\{R_m\} \sum_m R_m \rho R_m^\dagger = \rho$

We can write it as sum over n, n' , W_{nm} , sum over m , $W_{n'm}$, $W_{n'm}^\dagger$, $K_{n'}^\dagger$, $K_n \rho$, K_n^\dagger . Sum over n or m , $W_{nm} W_{n'm}^\dagger$ is sum over m $W_{nm} W_{n'm}^\dagger$ matrix and m n' element. Now you can see this is the product of W and W^\dagger , this is the product of W and W^\dagger and they're jointly n n' element. Now if we choose, it means W is isometric. Then $W^\dagger W$ is $\delta_{nn'}$. It means sum over m , $R_m \rho R_m^\dagger$ becomes sum over n n' $\delta_{nn'} K_n \rho K_n^\dagger$, which is same as sum over n $K_n \rho K_n^\dagger$.

(Refer slide time: 21:21)

$$\sum_m R_m \rho R_m^\dagger = \sum_{n, n'} W_{nm} K_n \rho K_n^\dagger W_{n'm}^\dagger$$

$$= \sum_{n, n'} \sum_m W_{nm} W_{n'm}^\dagger K_n \rho K_n^\dagger$$

$$\sum_m W_{nm} W_{n'm}^\dagger = \sum_m W_{nm} (W^\dagger)_{m n'}$$

$$= (W W^\dagger)_{n n'}$$

if $W W^\dagger = I \rightarrow W \rightarrow \text{isometric}$

$$(W W^\dagger)_{n n'} = \delta_{n n'}$$

$$\Rightarrow \sum_m R_m \rho R_m^\dagger = \sum_{n, n'} \delta_{n n'} K_n \rho K_n^\dagger$$

$$= \sum_n K_n \rho K_n^\dagger$$

So, in that way, if the two set of Kraus operators are related by an isometric matrix, then they will represent the same completely positive map and the choice of the Kraus operator is not unique. To find the set of Kraus operator for a given completely positive map ω , what we need to do is, we apply ω and find the kl element, sum over ij $M_{ij} \rho_{kl}$. So, from here we can find the matrix representation of Ω that is M , from M , we can find the H representation and these two are related as follows $M_{ij} \rho_{kl}$ equals $H_{ik} \rho_{jl}$. We have done it earlier, when we are talking about the positive maps and for since H is positive, we can show that for completely positive maps, H is positive and H is Hermitian of course, then H can be written as sum over n $\lambda_n k_n k_n^\dagger$ where λ_n are the eigenvalues and k_n are the orthonormal eigenvectors of H .

(Refer slide time: 22:30)

$$\rightarrow S_L(\rho)_{kcl} = \sum_{ij} M_{ij, ke} \rho_{ke}$$

Matrix Rep of S : M .

$$M \leftrightarrow H$$

$$M_{ij, ke} = H_{ik, je}$$

$\rightarrow H \geq 0$

And from here let's put tilde here for normalized and sum over n k_n k_n where these are unnormalized, k_n is defined as sum over λ square root of λ k_n tilde. k_n s are the unnormalized vectors. From here, H sum over n k_n λ_n , we can show that ω of ρ is sum over n k_n ρ k_n dagger where k_n are the folded version of the k_n s. It means we convert a vector into a matrix and then that is how we get the Kraus operator k_n . This is one choice of Kraus operator and this is in some sense, it is a canonical choice of Kraus operator because they are achieved from the spectral decomposition of the H matrix. Now, we can use the isometric transformation on k_n s and we can generate large number of set of operators which represent the same CP map and we can choose the most convenient Kraus operator for us.

(Refer slide time: 22:30)

$$\begin{aligned} \rightarrow H &> 0 \\ H &= \sum_n \lambda_n |k_n^{\sim}\rangle\langle k_n^{\sim}| \\ &= \sum_n |k_n\rangle\langle k_n| \\ |k_n\rangle &= \sqrt{\lambda_n} |k_n^{\sim}\rangle \\ S(\rho) &= \sum_n k_n \rho k_n^{\dagger} \\ k_n &= [|k_n^{\sim}\rangle] \text{ folded } |k_n^{\sim}\rangle. \end{aligned}$$

In that way, we can find the set of Kraus operator for any given completely positive map.
