Measurements: Introduction

Our topic in this lecture is the measurement. We have been mentioning measurements in some of the other contexts in several lectures earlier but this will be one full formal discussion about measurements. So, here we will be, there are several kind of measurements one which we are familiar with which is in the fourth postulate of quantum mechanics that's the projective measurements. They are also called von Neumann measurements. So, these are the measurements we have been talking about which gives you the Born rule, which gives you the state collapse postulate and the state after the measurement, those kind of things. This is the measurement which we are familiar with which comes in the fourth axiom of the quantum mechanics. This talks about the born probability rule of the measurement and the collapse of the wave function after the measurement.

So, all the other kind of measurements which we will be discussing will be related to the projective measurement in some other context, but they are more general, so they can be treated in a slightly more general way. So, the second one is like generalized measurement. So, in these generalized measurements, we will talk about many measurements like indirect measurement where we will not perform the measurement directly on the quantum system, but we will make it interact with another quantum system and perform measurement on the other one. So, in that way we are not directly measuring the quantum system under consideration, but we are measuring another quantum system which we have coupled with the desired quantum system. Then there are POVMs, they are called positive operator valued measurements and they contain mathematical structure of all the possible measurements on a quantum system.

(Refer slide time: 2:49)

Then we will have coarse grain measurements and then we will have weak measurements. We may not discuss all this kind of measurement, but they will be surely touched upon in the lecture. So, let us start with the von-Neumann measurement. So, we have an observable A , which is a Hermitian operator. And it has eigenvalues a_i and eigenvector $|a_i\rangle$, such that $A |a_i\rangle = a_i |a_i\rangle$.

This is its eigenvalue equation. Also, observable must be the Hermitian operators. The property about Hermitian operators is their eigenvalues are always real and their eigenvectors form an orthonormal basis. We are choosing the eigenvector to be normalized, although the eigenvalue equation does not care about the normalizations but we choose them to have norm one, then, one, if we have a quantum system in the state $|\psi\rangle$ then the probability of getting the outcome a_i , the probability of getting a_i is given by the Born probability rule which is $|\langle \psi | a_i \rangle|^2$. This is the Born rule. Second, once we have a_i outcome then the state $|\psi\rangle$ collapses to the eigen state $|a_i\rangle$, this is the collapse postulate.

(Refer slide time: 5:07)

So, the projective measurement is that if we want to observe if you want to measure an observable A where a small a_i 's are the eigenvalues and vector $|a_i\rangle$'s are the eigenvectors of

the observable A, then the probability of the i-th outcome is given by the Born rule which is $\langle \psi | a_i \rangle$ mod square. And after the measurement, the state of the quantum system collapses to the outcome eigenstate a_i . We can generalize this treatment in the following way. Let us define a projector P_n . So, a projector is an operator such that P_n^2 equals P_n .

This is the only definition of a projector. So, any operator P, if it satisfies $P^2 = P$, then it must be a projector. So, for example, we are defining P_n to be an outer product $|a_n\rangle\langle a_n|$. It means P_n^2 is $|a_n\rangle\langle a_n| |a_n\rangle\langle a_n|$, which is a scalar here, which is inner product of $|a_n\rangle$ with itself. And since $|a_n\rangle$ is normalized, this is 1.

We get an outer product $|a_n\rangle\langle a_n|$ and this is P_n . Therefore, P_n equals an outer product $|a_n\rangle\langle a_n|$ is a valid projector. Now, we can reformulate the two statements about the projective measurement that is Born rule that p of a_n is $\langle \psi | a_n \rangle$ mod square. This can be written now as $\langle \psi | P_n | \psi \rangle$. That becomes the new Born rule. Both are the same statement.

(Refer slide time: 6:10)

We can see that when we substitute P_n , we get an outer product $|a_n\rangle\langle a_n|$, $\langle \psi | a_n \rangle$ mod squared. So, we can write the Born rule in terms of the projector P_n . And the state collapse, $|\psi\rangle$ going to the projected state becomes $P_n |\psi\rangle$ divided by $\sqrt{\langle \psi | P_n | \psi \rangle}$. So, this becomes the collapse postulate. So, in this way by refining the projector P_n we can write both the statements of the projective measurement.

(Refer slide time: 7:12)

If we have not a pure state but a mixed state ρ which is given by sum over n $d_n |\phi_n\rangle\langle\phi_n|$. If you have a density matrix ρ , then the probability of getting m th outcome will be sum over n $d_n |\langle a_m | \phi_n \rangle|^2$. This is how the probability of m -th outcome, which is what we are just writing, short form as p_m , we call it p of a_m , is given by this. Now, in terms of projectors, it becomes sum over n $d_n |\langle a_m | \phi_n \rangle|^2$. And if you remember the cyclic property of the trace, this whole thing can be written as trace of $P_m \rho$. This also can be written as expectation value of P_m .

(Refer slide time: 8:10)

$$\begin{aligned} \rho &= \sum_n d_n |\phi_n\rangle\langle\phi_n| \\ p(a_m) &= \sum_n d_n \langle a_m | \phi_n \rangle \langle \phi_n | a_m \rangle \\ &= \sum_n d_n |\langle \phi_n | a_m \rangle|^2 \end{aligned}$$

Similarly, here also the probability this can be written as expectation value of P_m . P_m here. So, the probability of the outcome is the expectation value of the projector P_m . And the state collapse ρ going to $\tilde{\rho}$ after measurement becomes $P_m \rho P_m$ divided by p of a_m and that's nothing but $a_m a_m$. So, in that way by defining the projectors, we can reformulate the projective measurements in a much simpler, much concise way. But our definition of projector was $P^2 = P$. This is the definition of projector. Then if we take, let us say, a_1 outer product a_1 plus a_2 outer product a_2 , and let us call it P , then P^2 , since a_1 and a_2 are orthogonal, will also be a_1 outer product a_1 plus a_2 outer product a_2 .

(Refer slide time: 8:50)

$$\begin{aligned} p(a_m) &= \sum_n d_n \langle a_m | \phi_n \rangle \langle \phi_n | a_m \rangle \\ &= \sum_n d_n |\langle \phi_n | a_m \rangle|^2 \\ &= \sum_n d_n \langle \phi_n | P_m | \phi_n \rangle \\ &= \text{Tr}[P_m \rho] = \langle P_m \rangle \\ \rho \rightarrow \tilde{\rho} &= \frac{P_m \rho P_m}{p(a_m)} = |a_m\rangle\langle a_m| \end{aligned}$$

So, this is also a valid projector. So, it means we can have a measurement setup where we have state coming in, rho, and outputs are there. And there can be scenarios where we cannot distinguish between, let us say, a1 and a2. So, both of those outcomes give you the same, both of those cases will give you the same outcome. Similarly, you can have a bunch of other measurements which will give you one click.

(Refer slide time: 12:23)

$$P^2 = P; \quad P = |a_1\rangle\langle a_1| + |a_2\rangle\langle a_2|$$

$$P^2 = |a_1\rangle\langle a_1| + |a_2\rangle\langle a_2|$$

$$P_1 = \left\{ \sum_{n_1} |a_{n_1}\rangle\langle a_{n_1}| \right\}$$

$$P_2 = \left\{ \sum_{n_2} |a_{n_2}\rangle\langle a_{n_2}| \right\}$$

$$\{ P_n \}$$

$$\left\{ \frac{|HV\rangle - |VH\rangle}{\sqrt{2}} \right\}, \left\{ |HH\rangle, |VV\rangle, \left(\frac{|HV\rangle + |VH\rangle}{\sqrt{2}} \right) \right\}$$

So, it means you will have p1, which is a sum of many many sum over n1 an1 an1 and then you have other projector p2, which is sum over n2 an2 an2 and so on. You can have a set of many pn's which are not rank 1 projectors but more than rank 1 projector. And so, you can have a set of many pn's which are not rank 1 projectors but more than rank 1 projector. They can be rank 1 or more projectors. These kinds of measurements are called coarse grain measurements. In some scenarios where we cannot distinguish between many outcomes, then we see this kind of coarse grain measurement.

For example, when we have two photons coming in with different polarizations, when we merge them on a beam splitter, then the output can be either a symmetric state or an antisymmetric state of the two photons in the polarization ratio. So, they are called singlet and triplet. In a linear optical experiment, we cannot distinguish between the singlet and triplet generally, unless we put some extra effort. So, in those cases, the singlet state, which is given by the horizontal, vertical, minus vertical, horizontal, the two photons

being in different polarization, divided by root 2. This is antisymmetric state in the sample, if we interchange the two photons, we get the negative sign out.

And then we have triplet, where we have both photon in H or both photon in V or one in H other in V plus one in V other in H. This is the symmetric combination of the different polarization. So, this is a singlet and this is a triplet and this is a singlet state. Singlet state is the anti-symmetric state and triplet state is the symmetric state. Since the photons are bosonic in nature, so, in a linear optical experiment we cannot distinguish between these three states. So whenever we have any of this state we get the same click out and when we have this, we get another click so in that way we have one projector let's call this state as zero and this is one two and three state.

(Refer slide time: 13:02)

$$\left\{ \frac{|HV\rangle - |VH\rangle}{\sqrt{2}} \right\}, \left\{ |HH\rangle, |VV\rangle, \frac{|HV\rangle + |VH\rangle}{\sqrt{2}} \right\}$$

$$\underbrace{\hspace{10em}}_{|0\rangle} \quad \underbrace{\hspace{10em}}_{|1\rangle, |2\rangle, |3\rangle}$$

$$P_0 = |0\rangle\langle 0|$$

$$P = |1\rangle\langle 1| + |2\rangle\langle 2| + |3\rangle\langle 3|$$

So, we have one projector P_0 , which is 0 outer product 0 and other projector P_1 , which will be 1 projector 1 plus 2 projector 2 plus 3 projector 3. So, in that way, we have some physical examples of when more than one orthogonal state being a part of a projector. So, in these cases, what happens to the Born probability? So, the Born probability P of n is still given by the expectation value of the n th projector. We do not care whether this projector P_n is rank 1 projector or rank 2 projector or rank 3 projector.

What we mean by the rank is the number of non-zero eigenvalues. So, since P_n square is P_n , then the only eigenvalues it has are either 1 or 0 because the eigenvalues should satisfy the equation satisfied by the operator. So, P_n square minus P_n equals 0. So, only 0 and 1 can satisfy this equation. Now, how many ones we have and how many zeros we have will tell us what is the rank of the projector. So, when we have p to be an outer product an then it's rank one. When we have more than this, then we have rank two, three and four depending on how many non-zero ones we have. So, while defining this Born rule, the general Born rule, we do not care what is the rank of the projector under consideration but the probability is given by the expectation value of p_n , so if it is a pure

state it becomes $\psi P_n \psi$ and if it is a mixed state, then it becomes trace of ρP_n , this is for pure states and this is for mixed states.

(Refer slide time: 14:03)

$$P_n = \langle P_n \rangle \leftarrow \text{Born Rule.}$$

$$P_n^2 = P_n, \quad (1) \quad (0)$$

$$P = |a_n\rangle\langle a_n| \rightarrow \text{Rank 1.}$$

$$p_n = \langle \psi | P_n | \psi \rangle \rightarrow \text{pure}$$

$$= \text{Tr}[\rho P_n] \rightarrow \text{Mixed}$$

Now the collapse postulate can be written as ψ collapses to ψP_n divided by root $\sqrt{p_n}$ if it is a pure state and if it is a mixed state, ρ goes to ρP_n over root over $\sqrt{p_n}$. Till now in terms of the representation in terms of the expressions for the Born rule and the collapse state, there is no difference between rank 1 projector and rank 2 projector but or rank higher than projector, but one thing we have to be carefully is when P_n is a rank 1 projector then if P_n is a rank 1 projector, then ρ collapses to ρP_n over small $\sqrt{p_n}$, which will be an outer product $|a_n\rangle\langle a_n|$. It means it's a pure state. It means rank one projectors project any density matrix ρ to a pure state. But if it is rank more than one, let us say two, then we can write P_n to be $|a_{n1}\rangle\langle a_{n1}| + |a_{n2}\rangle\langle a_{n2}|$.

(Refer slide time: 15:17)

$$p_n = \langle \psi | P_n | \psi \rangle \rightarrow \text{pure}$$

$$= \text{Tr}[\rho P_n] \rightarrow \text{Mixed.}$$

Calculus: $|\psi\rangle \rightarrow \frac{P_n |\psi\rangle}{\sqrt{p_n}}$

$$P \rightarrow \frac{P_n \rho P_n}{p_n}$$

Then ρ collapses to ρP_n over $\sqrt{p_n}$, which is not a pure state. It is actually a mixed state, generally. Of course, if there is no component of $|a_{n2}\rangle$ or $|a_{n1}\rangle$ in ρ , then we can get pure state also or nothing. So, in that case, things will be different. But in general, for the projectors more than rank 1, the projected state will not be a pure state, it will be a mixed state.

(Refer slide time: 16:50)

$P_n \rightarrow \text{Rank } 1$
 $\rightarrow P_n P_n = P_n = |a_n\rangle\langle a_n|$ Pure state.

$\rightarrow \text{Rank } > 1$
 $\Rightarrow P_n = |a_{n1}\rangle\langle a_{n1}| + |a_{n2}\rangle\langle a_{n2}|$
 $\rightarrow P_n P_n = P_n \neq \text{Pure state}$ Mixed state.

Let us consider a set of projectors P_i , such that $P_i P_j = \delta_{ij}$. It means if i is not equal to j , then it is 0, the product is 0. If i is equal to j , then it is a projector. So, it is $P_i^2 = P_i$. And if sum over i P_i is identity, just let me remind you that identity is also a projector. It's a projector because identity squared is identity. So, identity is also a projector. And if sum over i P_i is identity, then it's called informationally complete set.

Set of projectors. So, this is a valid measurement basis. So, if you want to perform a complete measurement on the quantum system, we need to find one such set. One previous example of one regular example of such set is the set of the projector $|a_i\rangle\langle a_i|$, that will amount to the regular von-Neumann measurement. This is the regular projective measurement we have been talking about from the beginning of this course. Then other can be coarse-grain measurement where more than one projector combined, more than one projector combined to make rank more than one projector and then we get coarse-grain measurement. One very trivial example is a set of just one element, which is identity, which is also a projector, which satisfy all the conditions given above.

(Refer slide time: 19:00)

$\rightarrow \{P^{(i)}\}$ $P^{(i)} P^{(j)} = \delta_{ij}$ $\sum P^{(i)} = I$ \rightarrow Informationally complete Set of Projector \rightarrow Valid measurement basis.

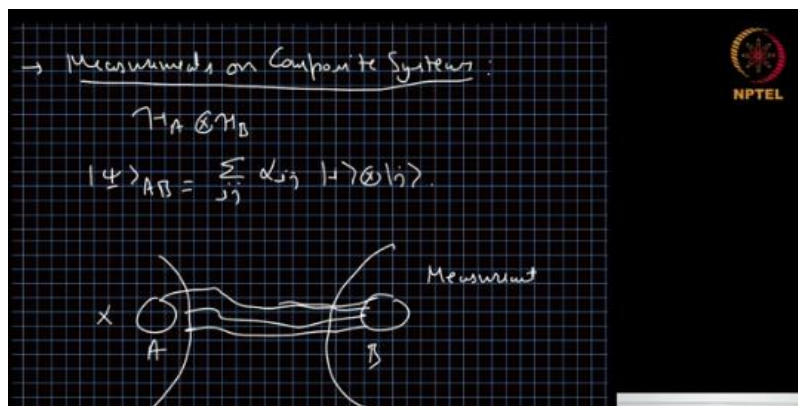

$\rightarrow \{|a_i\rangle\langle a_i|\} \rightarrow$ Regular Von-Neumann.

$\rightarrow \{I\} \rightarrow$ Mixed state.

So, this measurement will yield nothing. So, you have a state going in the setup and the state comes out. The probability of that happening is one and no information is captured about the system in this way. But this is a mathematically valid measurement. Next is measurement on composite system. Let us consider a bipartite system H_A tensor H_B .

For the sake of ease, we assume both of them are the same dimensional system and same basis they have. So, an arbitrary state $|\psi\rangle_{AB}$ can be written as $\sum_{i,j} \alpha_{ij} |i\rangle \otimes |j\rangle$. An arbitrary state can be written in this form where i and j are the computational basis. It's a two, it's a bipartite system, it's a composite system, so we can think of it like there are two quantum systems A and B and they are in some joint state. This is just artistic representation of two entangled or joint quantum system. But they can exist physically apart from each other. So, this can be in one lab and this can be in another lab. So, there is a possibility that we perform measurement on subsystem B , but not on subsystem A . So, how do we represent such scenarios where we have a composite system and we perform measurement only on a subsystem of it.

(Refer slide time: 20:37)

So, partial measurements, let us call it so let us say the measurement basis we are choosing on subsystem B is $|\phi_j\rangle$ basis. It's the orthonormal basis, it's a rank one projector. So, it will belong to rank one projector. So when we perform measurement on subsystem B , so the projectors we can think of a, we can say that there are P_i projectors or P_j projectors which are given by $|\phi_j\rangle \langle \phi_j|$. So, in general the joint measurement of A and B will be the measurement on subsystem A and measurement on subsystem B . Since we are not doing anything on A , the projector on A can be thought of

as just identity projector on A and P_j 's on B. So, this is the basis in which we will be performing measurements. The total basis will be identity tensor p_j . We can see that sum over j identity tensor p_j equals identity tensor sum over j P_j .

(Refer slide time: 22:09)

This is equal to identity tensor identity. So, this satisfies the criteria of the informationally complete basis in terms of projector. Next, we can see that identity tensor P_i times identity tensor P_j can be will be identity tensor $P_i P_j$ which is identity tensor δ_{ij} and these are orthonormal basis. So, if this is δ_{ij} , it becomes identity tensor $P_i \delta_{ij}$, so these set of projectors satisfy all the conditions of an informationally complete basis, so this is a valid measurement basis to perform on the subsystem, on the composite system AB. So, the measurement will yield ψ_{AB} going to after measurement identity tensor P_n on ψ divided by root P_n where root P_n is the probability of the outcome that is given by ψ identity tensor P_n . Now we can see that, let us call it $\tilde{\psi}$ which is the projected state will be $1/\sqrt{P_n} \sum_{ij} \alpha_{ij} |i\rangle |j\rangle$ and there is a let me write identity tensor P_n i tensor j.

(Refer slide time: 22:47)

This will be $\frac{1}{\sqrt{p_n}} \sum_{ij} \alpha_{ij} |i\rangle \otimes |j\rangle$, p_n is $\langle \Phi | P_n | \Phi \rangle$, outer product $|\Phi\rangle \langle \Phi|$. It can be simplified, $\frac{1}{\sqrt{p_n}} \sum_{ij} \alpha_{ij} |i\rangle \otimes |j\rangle$, and we can take this also and it is $|i\rangle \otimes |\chi_n\rangle$. Now if we look at it carefully, this can be written as $|\chi_n\rangle \otimes |\phi_n\rangle$ where $|\chi_n\rangle$ is $\frac{1}{\sqrt{p_n}} \sum_{ij} \alpha_{ij} |i\rangle$ and $|\phi_n\rangle$ is the state of the subsystem B after the measurement. So, from the subsystem B point of view, after the measurement, the state collapse to the eigenstate of the outcome, $|\phi_n\rangle$, because $|\phi_n\rangle$ was the outcome we got. And in response, the state of the subsystem A also collapse to some state and that state is given by $|\chi_n\rangle$ which depends on the outcome of the subsystem A or subsystem B that is $|\phi_n\rangle$ and the coefficient, joint coefficient of A and B so measurement on B affects the outcome of A also. That is one thing that the measurement on AB affects the state of A and this is what is used in many of the quantum computation and information protocols.

(Refer slide time: 25:29)

$$|\Phi\rangle_{AB} \rightarrow \frac{(I \otimes P_n) |\Phi\rangle_{AB}}{\sqrt{p_n}}$$

$$p_n = \langle \Phi | I \otimes P_n | \Phi \rangle$$

$$|\Phi\rangle = \frac{(I \otimes P_n)}{\sqrt{p_n}} \sum_{ij} \alpha_{ij} |i\rangle \otimes |j\rangle$$

$$= \frac{1}{\sqrt{p_n}} \sum_{ij} \alpha_{ij} (I \otimes |a_n\rangle \langle a_n|) |i\rangle \otimes |j\rangle$$

$$= \frac{1}{\sqrt{p_n}} \sum_{ij} \alpha_{ij} \langle a_n | j \rangle |i\rangle \otimes |a_n\rangle$$

$$= |\chi_n\rangle \otimes |a_n\rangle$$

$|\chi_n\rangle = \frac{1}{\sqrt{p_n}} \sum_{ij} \alpha_{ij} \langle a_n | j \rangle |i\rangle$

State of subsystem A

The quantum teleportation is performed using this principle. Another interesting thing to notice here is after we perform measurement on subsystem A, the state type AB which was the initial state, does not matter what was initially the state, the outcome after measurement is the product state. This is a product state. Or in other words, it is a separable state, non-entangled. So, a measurement on subsystem A, a projective measurement rank one projective measurement on subsystem A yields a separable state

between A and B. it destroys all the entanglement if there was any. We can generalize this result to the mixed state also but those are trivial exercises, I will recommend everyone to try those things at home.

What will happen if what would have happened if our projector was a rank two projectors. It means P_n let us say was $\phi_{n1}, \phi_{n1} + \phi_{n2}, \phi_{n2}$. So, we want to explore the case when P_n is rank two projector instead of rank one projector. In that case, ψ_{AB} will go to $\tilde{\psi}$ which is again given by $\frac{1}{\sqrt{P_n}} \sum_{ij} \alpha_{ij} |i\rangle \otimes |j\rangle$ tensor p_{nj} . Now p_{nj} is $\phi_{n1} \phi_{n1j} + \phi_{n2} \phi_{n2j}$. Let us call it $p_{n1j} + p_{n2j}$ let us say $r_{n1j} + r_{n2j}$ and we can substitute it there, so our side delta will be $\frac{1}{\sqrt{P_n}} \sum_{ij} \alpha_{ij} |i\rangle \otimes (r_{n1j} \phi_{n1} + r_{n2j} \phi_{n2})$. Now, the issue here is this state depends on both n which is $n1$ and $n2$ and j . We cannot separate this in terms of like in n and j index, we cannot write this state which is independent of j . So, in that way, we cannot write the whole state here as some χ tensor some ϕ_n . Hence, this is an entangled state.

(Refer slide time: 29:27)

$$|\Psi_{AB}\rangle \rightarrow |\tilde{\Psi}\rangle = \frac{1}{\sqrt{P_n}} \sum_{ij} \alpha_{ij} |i\rangle \otimes P_n |j\rangle$$

$$P_n |j\rangle = |\phi_{n1}\rangle \langle \phi_{n1}| j\rangle + |\phi_{n2}\rangle \langle \phi_{n2}| j\rangle$$

$$= r_{n1j} |\phi_{n1}\rangle + r_{n2j} |\phi_{n2}\rangle$$

$$|\tilde{\Psi}\rangle = \frac{1}{\sqrt{P_n}} \sum_{ij} \alpha_{ij} |i\rangle \otimes (r_{n1j} |\phi_{n1}\rangle + r_{n2j} |\phi_{n2}\rangle)$$

← n, j Entangled state

$$= |\chi\rangle \otimes |\phi_n\rangle$$

Unlike the rank 1 projector where we got a separable state, if the measurement is done in a coarse grain manner, then the resultant state need not be a separable state. In fact, in general, it will be an entangled state. So, this is the crucial difference between the rank 1 and rank 2 projectors when they apply on a subsystem. Next, we will be discussing the indirect measurement. An indirect measurement consists of a system on which we want to perform the measurement.

Let us represent the system with S . It's a Hilbert space HS and the initial state is ρ_S . And we want to perform measurement on ρ_S . To assist in the indirect measurement,

we need a probe. Often, we call it ancilla A. The Hilbert space of the ancilla is H_A . And the initial state is ρ_A . We will choose ρ_A according to our convenience so that we can make the measurement easily and in a more effective way. Next is the coupling or interaction between A and S. The interaction between any quantum system given by a unitary transformation, let us represent it by U. It is a unitary acting on H_A and H_S together in a joint manner. So, the total Hilbert space H is H_A tensor H_S .

(Refer slide time: 31:02)

So, the unitary U belongs to the set of operators setting on H. So, initially our total state ρ is ρ_A tensor ρ_S . After the interaction ρ tilde becomes U ρ_A tensor ρ_S U dagger. And after that, we perform measurement on the Ancilla. So, to perform measurement, let us say we perform projective measurements without complicating things. So, we choose the basis of the measurement to be n basis. So, this is the orthonormal basis in the Hilbert space of the ancilla.

(Refer slide time: 31:51)

When, in the case of nth outcome, we get the outcomes, the state of the system and ancilla collapses to the following state, P_n tensor identity, U ρ_A tensor ρ_S U dagger, P_n tensor identity over the probability. We will talk about the probability P_n in some time, but the projector P_n is nothing but the projector over the state n. Let us say ρ_A , the ancilla state is a pure state given by ψ, ψ . In that case ρ tilde n becomes P_n tensor identity u $\psi \psi$ tensor ρ_S u dagger P_n tensor identity. If we replace P_n with n

ρ_n with $n \times n$ and then we defined K_n to be n tensor identity, U n tensor identity. Then this becomes the operator acting on the Hilbert space of the system. This is the Kraus operator.

(Refer slide time: 32:56)

\rightarrow Perform Measurements on A .
 $\{k_n\}$ ONB in H_A
 n -th outcome
 $\tilde{\rho}_n = \frac{(P_n \otimes I) (U (\rho_A \otimes I) U^\dagger) (P_n \otimes I)}{p_n}$
 $P_n = I_n \otimes I_n$
 $P_A = I_4 \otimes I_4$

We have discussed this thing in the completely positive maps. Then ρ_n can be written as n out of product n tensor $k_n \rho_n k_n^\dagger$. There was a probability P_n down there and there is a probability P_n . Then P_n becomes the trace of ρ_n which is same as trace of $k_n \rho_n k_n^\dagger$. So, this is the probability of the outcome or the measurement outcome and this is the state after collapse. What we have done is we have extended our system of interest the Hilbert space of the system H_S to H_S tensor H_A or H_A tensor H_S .

(Refer slide time: 34:21)

$\tilde{\rho}_n = \frac{(I_n \otimes I) (U (I_4 \otimes P_n) U^\dagger) (I_n \otimes I)}{p_n}$
 $k_n = \langle n | \otimes I \ U \ | m \rangle \otimes I \in \mathcal{S}(H_S)$
 $\tilde{\rho}_n = I_n \otimes I \otimes \frac{k_n \rho_n k_n^\dagger}{p_n}$
 $p_n = \text{Tr}[k_n \rho_n k_n^\dagger]$

So, we have converted a simple system into a composite system and after that we have utilized a unitary transformation U to create interaction between system and the ancilla. Following that, we have performed a von Neumann measurement on the ancilla and the effect of that can be seen on the system S in the following form that the state of the system ρ_s goes to $P_n \rho_s P_n^\dagger$ over P_n upon measurement. This is a normalized

state, so this is the result of an indirect measurement on the quantum system on the quantum system S . This outcome happens with the probability P_n . So, the total average outcome state of the system can be written as sum over n P_n times $K_n \rho_S K_n^\dagger$ over P_n will be $\sum_n K_n \rho_S K_n^\dagger$.

This is the average outcome state after the complete measurement. K_n 's are called measurement operator. The trace of the outcome state should be always one because it's a valid state. This implies that, which remains exercise, which we have already done also that sum over n $K_n^\dagger K_n$ should be identity. This is an additional condition over the measurement operators. Now, what we have done, what is the difference between the projective measurement and the indirect measurement? In the projective measurement, we had a set of projectors P_n , such that sum over n , P_n equals identity and $P_i P_j$ equals $P_i \delta_{ij}$.

(Refer slide time: 37:13)

Handwritten notes on a grid background:

- $\rho_S \rightarrow \frac{K_n \rho_S K_n^\dagger}{p_n}$ upon measurement. \rightarrow Indirect Measurement on Q.S. S .
- $\rho_{out} = \sum_n p_n \left(\frac{K_n \rho_S K_n^\dagger}{p_n} \right)$
- $\rho_o = \sum_n K_n \rho_S K_n^\dagger$
- $\rightarrow K_n \rightarrow$ Measurement operators.
- \rightarrow Trace $\rho_{out} = 1 \Rightarrow \sum_n K_n^\dagger K_n = I$

They are orthonormal. So, this is the projective measurement. In the indirect measurement, we have set of K_n such that sum over n $K_n^\dagger K_n$ equals identity and that is all. In the projective measurements, the probability P_n was given by expectation value of P_n and the state ρ_n was after the measurement was $P_n \rho P_n$ over P_n . In the indirect measurement, the probability P_n is given by $K_n \rho K_n^\dagger$ trace which also can be written as trace of $K_n^\dagger K_n \rho$ or expectation value of $K_n^\dagger K_n$ and the state after collapse is given by $K_n \rho K_n^\dagger$ over K_n .

Projective Measurement:

$$\rightarrow \{P_n\} \quad \sum_n P_n = I \quad P_i P_j = P_i \delta_{ij}$$

$$h_n = \langle P_n \rangle$$

$$p_n = \frac{P_n P P_n}{p_n}$$

Indirect Measurement:

$$\{K_n\} \quad \sum K_n^\dagger K_n = I$$

In that way, there are certain differences in projective measurement and indirect measurement, but mathematically they are very much alike in spirit and we can see that the projective measurement is a subclass of the indirect measurement. We can choose K_n 's in such a way that they become projective measurement. Till now we have seen that given a unitary, which is the interaction between the ancilla and the system and the initial state of the ancilla and the measurement basis will yield a set of Kraus operators K_n or measurement operators K_n , which will give us the indirect measurements on a system, or generalized measurement on a system. The question can be asked, for a given set of measurement operator K_n , can we find a unitary operator U , a state of the ancilla, initial state of the ancilla ψ and the measurement basis n corresponding to K_n . So, to answer this thing, we see that K_n was defined as N tensor identity $U \psi$ tensor identity.

(Refer slide time: 40:30)

$$\rightarrow U, |\psi\rangle, \{|n\rangle\} \rightarrow \{K_n\}$$

$$\rightarrow \{K_n\} \text{ can we find } U, |\psi\rangle, \{|n\rangle\}?$$

$$K_n = \langle n | \otimes I U (|\psi\rangle \otimes |0\rangle)$$

let $\{|n\rangle\}$ computational Basis.

Let us say n is the computational value. It means vector n is defined as a vector of zeros with only one 1 at n th location. And let us say ψ is the zero state. And we know that any arbitrary U which is acting on a composite system can be written as $\sum_{ij} U_{ij} |i\rangle\langle j|$ where U_{ij} are the operators acting on the system. Or in other way, we can write it as $U_{00}, U_{01}, U_{02}, U_{10}, U_{11}, U_{12}$, these are all operators.

So, we have written U , capital U as the matrix of matrices. Then we can see that $n \times n$ U , n tensor identity, $U \otimes I$ tensor identity is $U \otimes I$, which is by definition $K \times n$. So, if we had a U , then the first column of vector, first column of operator is equal to the $K \times n$ we have as measurement operators. So, for a given set of measurement operators, we can choose a U such that the first column is the column of the measurement operators, K_0, K_1 up to K_n and rest of the matrix is, can be chosen arbitrarily in such a way, let us say the rest of the matrix is R , which you can choose R in such a way that U is a unitary. So, we say R , we choose in such a way U is unitary.

(Refer slide time: 43:00)

$|\psi\rangle = |0\rangle$
 $U = \sum_{ij} |i\rangle\langle j| \otimes U_{ij}$
 $U_{ij} \in \mathbb{C}(K \times n)$

$$= \begin{bmatrix} U_{00} & U_{01} & U_{02} & \dots \\ U_{10} & U_{11} & U_{12} & \dots \\ \vdots & \vdots & \vdots & \ddots \end{bmatrix}$$

 $\langle n| \otimes \langle 0| U |0\rangle \otimes |0\rangle = U_{n0} = K_n$

$$U = \begin{bmatrix} K_0 \\ K_1 \\ \vdots \\ K_n \\ R \end{bmatrix} \quad R \rightarrow U \rightarrow U \text{ unitary}$$

 $|0\rangle, |n\rangle$

And this can always be done. So, there is a huge choice in terms of R for a given set of measurement operators K_n , that U is a unitary and here, what we have assumed is the initial state of the system is, ancilla is zero and the measurement basis is the computational basis. Of course, if we change these things then U will also change but since our task is to find the simplest U possible, we will choose the simplest initial state and simplest basis, but if the given problem demands something else, then we can choose those also and our unitary matrix will also change. So, in that way for a given set of measurement operators $K_0, k=K_1$ up to K_n , we can always construct a unitary U for the initial state 0 and the measurement basis n such that it gives you the indirect measurement.
