Measurement: Optical Scheme for POVM

The topic today is the optical scheme to implement POVM measurement. So, here, as usual, we will consider the polarization qubits. And we will also consider the path degree of freedom of the photon. So, that will be dual rail qubit or some other form of qubit. So, we'll see when it is revealed.

The state $|\psi\rangle$ of the qubit can be written as $\alpha|h\rangle + \beta|v\rangle$ where α and β are complex numbers and h and v are horizontal and vertical polarizations $|\alpha|^2 + |\beta|^2 = 1$ that is for the normalization now we take a beam splitter. And this is a polarizing beam splitter. So, what it does is if the horizontal polarization is coming in it will let it go and if vertical polarization is coming in then it will reflect it so vertical will go vertically up and horizontal will go horizontally but horizontal will go straight, so, if we send state $|\psi\rangle$ here then h will go here and we will go there and we perform measurement and we get the $|\alpha|^2$ and $|\beta|^2$. This whole thing can be thought of in the following way. We have one path of input path of the beam splitter. Let us call it state A . If the photon is coming in this path, then we are calling it in the state A and there is another path which we are not using for the time being, but there was a path.

(Refer slide time: 2:50)

So, that's state b. These are input. The output we are naming the straight path as same path and the reflected path as a different path. So, output a and b we have. So, the initial state can be thought of as state of a photon in two degrees of freedom, one is the polarization other is the position basis. So the total state, initial state input is psi tensor a, so psi is the polarization state of the photon and a is the spatial state path information, that is equal to alpha H_a plus beta V_a. Now, when we pass it through the polarizing insulator, then H_a goes to H_a, it will remain in the same part, but V_a will go to V_b. H_b will remain same, H_b and V_b will become V_a.

(Refer slide time: 4:24)

↑ |b>

→ Input: $|\psi\rangle @ |a\rangle = \alpha |H\rangle |a\rangle + \beta |V\rangle |a\rangle$

→ PBS:

- $|H\rangle |a\rangle \rightarrow |H\rangle |a\rangle$
- $|V\rangle |a\rangle \rightarrow |V\rangle |b\rangle$
- $|H\rangle |b\rangle \rightarrow |H\rangle |b\rangle$
- $|V\rangle |b\rangle \rightarrow |V\rangle |a\rangle$

$|\psi\rangle @ |a\rangle \xrightarrow{\text{PBS}} \alpha |H\rangle |a\rangle + \beta |V\rangle |b\rangle$

→ Perform intensity measurement in $\{|a\rangle, |b\rangle\}$

$p_a = |\alpha|^2 = p_H \quad p_b = |\beta|^2 = p_V$

Now, what is the action of the polarizing beam splitter on psi tensor a? So, psi tensor a will go to alpha, H_a remains H_a plus V_a becomes V_b. After that, we perform measurement, perform intensity measurements in a and b That is, we put detectors which do not discriminate between the polarization, but they just see whether the photon was in a or b. So, we are performing measurement in the spatial modes. So, whether the photon was in a or b, we perform measurement that, and accordingly, we know that the probability of getting the photon in a is alpha mod square and probability of getting in b is beta mod square.

And which is same as probability of getting in H and probability of getting in V. So, what we have done here is we had a system that is the polarization. We have an ancilla that is a special degree of freedom, bar degree of freedom. And we take these two systems

together. We use a unitary transformation to couple those two and then we perform measurement on the ancilla.

And in that fashion, we are performing measurement on the polarization indirectly. But here the interaction was very very strong between the system and the ancilla. That's why this effectively became a projective measurement. Now how do we perform POVM on such system? On the same system, if we want to perform POVM, how will it work?

For simplicity, we take a POVM, where the measurement operators are K_0 and K_1 , such that $K_0^\dagger K_0 + K_1^\dagger K_1 = \text{identity}$. These are measurement operators, these are not effects. In fact, for these given measurement operators, $K_0^\dagger K_0$ will be one effect and $K_1^\dagger K_1$ will be another effect. So, for given measurement operator it is easy to find the effects. Now we want to find an optical setup which can implement this measurement operator.

So, from our earlier treatment when we are given measurement operators we know that we have to consider system and ancilla, the total Hilbert space will be the Hilbert space of the ancilla tensor Hilbert space of the system. We have to choose the state of the ancilla $|\psi_a\rangle$, initial state to be zero state, in this case it will be just path a and we have to have a unitary acting on the two and the unitary is chosen in such a way that the first block is k_0 second block is k_1 and then there are two blocks let us call them U_{12} and U_{22} . All of these four are 2 by 2 matrices K_0 and K_1 are given to us. U_{12} and U_{22} are arbitrary in such a way that the total matrix U becomes unitary. So, let us say we have U_{12} and U_{22} .

(Refer slide time: 6:50)

\rightarrow Measurement operators $\{K_0, K_1\}$
 $K_0^\dagger K_0 + K_1^\dagger K_1 = I$
 $\rightarrow U = U_A \otimes U_S$
 $|\psi_A\rangle = |a\rangle$

$$U = \begin{bmatrix} K_0 & U_{12} \\ K_1 & U_{22} \end{bmatrix}$$

Now, how to implement this arbitrary unitary on the polarization and path degree of freedom in a combined fashion is a challenge. To let us tackle that problem first, let us say we are given a unitary U , which is of the form $A B C D$ where $A B C$ and D are two

by two matrices complex matrices such that the total U is a unitary so if U is a unitary then U times U dagger which is A. Sorry, my notations are slightly different. I want to stick to them. BC, BCD, A dagger, B dagger, C dagger and D dagger. The product will be AA dagger plus BB dagger. A C dagger plus B D dagger the complex, the Hermitian conjugate of that and C C dagger plus D D dagger.

(Refer slide time: 9:04)

$$U = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \quad A, B, C, D \text{ } 2 \times 2 \text{ matrices}$$

$$U U^\dagger = \begin{bmatrix} A & B \\ C & D \end{bmatrix} \begin{bmatrix} A^\dagger & C^\dagger \\ B^\dagger & D^\dagger \end{bmatrix}$$

$$= \begin{bmatrix} AA^\dagger + BB^\dagger & AC^\dagger + BD^\dagger \\ (C^\dagger) & CC^\dagger + DD^\dagger \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

$AA^\dagger + BB^\dagger = I \quad CC^\dagger + DD^\dagger = I$

So, this is the matrix we get when we multiply U with U dagger in terms of a b c and d matrices and we know this must be equal to identity and identity and zero and zero two by two identity two by two zero two by two zero and two by two identity, so, from here we get a information that A A dagger plus B B dagger must be identity and same as C C dagger plus D D dagger. This implies that A A dagger equals 1 minus B B dagger and C C dagger equals 1 minus D D dagger. So, it means A A dagger commute with B B dagger. Similarly, CC dagger commutes with DD dagger. If two operators commute, then there must be a common unitary which can diagonalize both of them, so it means we have L1 A A dagger L1 dagger. Since A times A dagger is a positive and matrix positive operator so the eigenvalue will be real so we are writing diagonal matrices as Da square so it can be real and positive matrix.

(Refer slide time: 10:28)

$$\Rightarrow AA^\dagger = I - BB^\dagger \quad CC^\dagger = I - DD^\dagger$$

$$\Rightarrow [AA^\dagger, BB^\dagger] = 0 \quad [CC^\dagger, DD^\dagger] = 0$$

$$L_1 AA^\dagger L_1^\dagger = D_A^2 \quad L_2 CC^\dagger L_2^\dagger = D_C^2$$

$$L_1 BB^\dagger L_1^\dagger = D_B^2 \quad L_2 DD^\dagger L_2^\dagger = D_D^2$$

Similarly, $L_1 B B^\dagger L_1^\dagger$ is D_B square. Here we can have difference $L_2 C C^\dagger L_2^\dagger$ as D_C square and $L_2 D D^\dagger L_2^\dagger$ as D_D square. For the time being they just look mathematical but trust me this will become very very interesting result soon. Till now, we just use $U U^\dagger$, if we use $U^\dagger U$ equals identity that will be $A^\dagger C^\dagger B^\dagger D^\dagger A B C D$. It becomes $A^\dagger A$ plus $C^\dagger C$. We don't care about the off diagonal terms, we did not use it in the previous one, so we will not use it here $B^\dagger B$ plus $D^\dagger D$, something here, something here and this must be equal to identity, identity is zero zero. From here we can see that $A^\dagger A$ commute with $D^\dagger C$ and $D^\dagger B$ commute with $D^\dagger D$. It means we can have R_2 , some unitary R_2 , $A^\dagger A$ equals R_2^\dagger equals D_A square, the spectrum of $A^\dagger A$ and $A^\dagger A$ will remain same in this case. And $R_2 C^\dagger C$, $R_2 B^\dagger B$, R_2 , that was R_1 , sorry.

(Refer slide time: 13:56)

$$U^\dagger U = \begin{bmatrix} A^\dagger & C^\dagger \\ B^\dagger & D^\dagger \end{bmatrix} \begin{bmatrix} A & B \\ C & D \end{bmatrix}$$

$$= \begin{bmatrix} A^\dagger A + C^\dagger C & - \\ - & B^\dagger B + D^\dagger D \end{bmatrix} = \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

$$\Rightarrow \begin{cases} [A^\dagger A, C^\dagger C] = 0 \\ [B^\dagger B, D^\dagger D] = 0 \end{cases}$$

$$\begin{aligned} R_1 A^\dagger A R_1^\dagger &= D_A^2 & R_2 B^\dagger B R_2^\dagger &= D_B^2 \\ R_2 C^\dagger C R_2^\dagger &= D_C^2 & R_2 D^\dagger D R_2^\dagger &= D_D^2 \end{aligned}$$

$$\Rightarrow \begin{cases} W_1 X X^\dagger W_1^\dagger = D_x^2 & W_2 X^\dagger X W_2^\dagger = D_x^2 \\ W_1 X W_2^\dagger = D_x & \rightarrow \text{Singular value dec.} \end{cases}$$

The naming does not matter, but I just want to be consistent with the not so that later on if we use them, we don't make a mistake. D_B squared and $R_2 D^\dagger D R_2^\dagger$ equals $D D$ squared. Now if let us say if you have a unitary W such that W_1 let us say, such that $X X^\dagger W_1^\dagger W_1 X$ is D_X square and $W_2 X^\dagger X W_2^\dagger$ equals D_X square D_X square, then we can write $W_1 X W_2^\dagger$ as D_X . This is called singular value decomposition. One should read the proof of this, this is very beautiful theorem so if we have two unitary operators W_1 and w_2 which diagonalizes $X X^\dagger$ and $X^\dagger X$. Then W_1 and W_2 are the left and right eigenvectors of X and we can diagonalize X in

this fashion and we get D_x which is the matrix of single value diagonal matrix and this theorem holds for any dimension of X , X need not be one square matrix it can be rectangular matrix it can be anything so why we are measuring this thing because, because from our analysis so far, we have L_1 which diagonalizes AA^\dagger and we have R_1 which diagonalizes $A^\dagger A$.

So it means we have $L_1 A R_1^\dagger = D_A$. Similarly, we have L_1 diagonalizing B and R_2 diagonalizing $B^\dagger B$. So, $L_1 B R_2^\dagger = D_B$. $L_2 C R_1^\dagger = D_C$ and $L_2 D R_2^\dagger = D_D$. So, D was R_2 here and L_2 and D_2 .

(Refer slide time: 16:06)

$$\begin{aligned}
 L_1 A R_1^\dagger &= D_A & L_2 C R_1^\dagger &= D_C \\
 L_1 B R_2^\dagger &= D_B & L_2 D R_2^\dagger &= D_D \\
 \Rightarrow A &= L_1^\dagger D_A R_1 & B &= L_1^\dagger D_B R_2 \\
 C &= L_2^\dagger D_C R_1 & D &= L_2^\dagger D_D R_2 \\
 \Rightarrow U &= \begin{bmatrix} L_1^\dagger D_A R_1 & L_1^\dagger D_B R_2 \\ L_2^\dagger D_C R_1 & L_2^\dagger D_D R_2 \end{bmatrix} \\
 &= \begin{bmatrix} L_1^\dagger & 0 \\ 0 & L_2^\dagger \end{bmatrix} \begin{bmatrix} D_A & D_B \\ D_C & D_D \end{bmatrix} \begin{bmatrix} R_1 & \\ & R_2 \end{bmatrix}
 \end{aligned}$$

So, what we have is A can be written as $L_1^\dagger D_A R_1$. B can be written as $L_1^\dagger D_B R_2$. C is $L_2^\dagger D_C R_1$ and D to be $L_2^\dagger D_D R_2$. This implies that U can be written as $L_1^\dagger D_A R_1$, $L_1^\dagger D_B R_2$, $L_2^\dagger D_C R_1$ and $L_2^\dagger D_D R_2$. Or we can write it as protocol C matrices, that is L_1^\dagger , L_2^\dagger , 0 , 0 , D_A , D_B , D_C , and D_D , R_1 , R_2 .

Now, for a moment, we should consider what we have done so far. We have a two-dimensional Hilbert space of the polarization qubit and two-dimensional Hilbert space of the path states. So, the base series we have chosen is H_A tensor H_B , is the total Hilbert space. So, the basis is aH , aV , bH , bV . So, it means the L_1 vector is acting on state A tensor ψ , where ψ is a polarization state, but the path is fixed A . So, L_1 is acting only in the A subspace.

Similarly, L2 is acting only in the B subspace. Similarly, R1 is acting only on A subspace, the subspace corresponding to A and R2 is acting on the state with B sub space. So these L1, L2, R1, R2 are the unitary operators acting on the polarization state of light but when they are in specific path. So R1 and L1 will act on polarization when they are in path A and R2 and L2 will act on polarization when they are in path B. So these are operations acting only on the polarization qubits but in a specific path. And this is a unitary.

(Refer slide time: 17:02)

$$= \begin{bmatrix} L_1^+ & 0 \\ 0 & L_2^+ \end{bmatrix} \begin{bmatrix} D_1 & 0 \\ 0 & D_2 \end{bmatrix} \begin{bmatrix} R_1 & 0 \\ 0 & R_2 \end{bmatrix}$$

$|a\rangle|H\rangle, |a\rangle|V\rangle, |b\rangle|H\rangle, |b\rangle|V\rangle$
 $R_1, L_1^+ |a\rangle|B_1\rangle$
 $R_2, L_2^+ |b\rangle|B_2\rangle$

L1 and R2 are unitary. R1 and R2 are unitary. So, the total matrix is also unitary. Total matrix is also unitary. This one and this one is also unitary.

And U is unitary. So, this must be unitary in the middle. Now, let us consider, let us analyze the matrix of diagonals. Matrix of diagonals is DA. Let me, DA was the matrix of eigen, singular values of matrix A. Let us call them A1, A2, 2 by 2 matrix and wherever I do not write an element, they are 0.

Then we have B1, B2, we have C1, C2 and D1, D2. And it is a unitary matrix. First condition of a unitary matrix is every column and every row must be normalized. And A, B, C, D, all of the elements are real here. It means we have a1 square plus c1 square equals identity 1.

This implies that we can assume a1 is cos of theta and b1 is, or c1 is sine of theta. Okay, we are fixing the sign here then this is what was about the first column now first row says a1 square plus b1 square is 1 then we know a1 is cos theta this implies that b1 must be sine theta but it could be minus sin theta also so instead of that we just say b1 square is sine square theta. Now, if we consider this the third column it becomes b1 square plus d1 square is 1. This implies that d1 it can be d1 square is cos theta cos square theta similarly we can do with a2 c2 b2 d2 and instead of theta we can say theta 1 here and theta 2 for the other one, so the matrix becomes theta 1 and cos of theta 2 plus minus sine of theta 1

we have to choose whether it is plus or minus and plus minus sine of theta 2. Then sine of theta 1 sine of theta 2 and cos of theta 1 plus minus and plus minus cos of theta 2 this is the form of the matrix we have the first one we can choose on our wish but other times we cannot choose arbitrarily. Now, if we analyze it further, it is very straightforward, but it might take a lot of time in the lecture to prove it.

(Refer slide time: 20:14)

The image shows a chalkboard with handwritten mathematical derivations. At the top, a 2x2 matrix is shown with elements a_1, b_1, c_1, d_1 in the first row and a_2, b_2, c_2, d_2 in the second row. To the right of the matrix, three equations are listed: $a_1^2 + c_1^2 = 1 \Rightarrow a_1 = \cos \theta_1, c_1 = \sin \theta_1$; $a_1^2 + b_1^2 = 1 \Rightarrow b_1 = \sin \theta_1$; and $b_1^2 + d_1^2 = 1 \Rightarrow d_1 = \cos \theta_1$. Below this, a larger matrix is shown with elements $\cos \theta_1, \pm \sin \theta_1, \sin \theta_1, \pm \cos \theta_1$ in the first row and $\pm \sin \theta_2, \cos \theta_2, \pm \sin \theta_2, \pm \cos \theta_2$ in the second row. The NPTEL logo is visible in the top right corner of the chalkboard image.

But if we look at it very carefully, we will see that if these have to be plus sign, then they must be negative sign here. So, these two should have opposite signs. And if we want the whole thing to be unitary, then and this vector to be orthogonal to this vector, then this must be plus. So, our matrix of diagonals will take this form cos of theta 1, cos of theta 2 in the first block, minus sin of theta 1, minus sin of theta 2, sin of theta 1, sin of theta 2 and cos of theta 1, cos of theta 2. This becomes our canonical form for the matrix of diagonals.

Since it is a matrix of cosines and sines, so it is called CS matrix. And with this, our unitary, which is L_1 dagger direct some L_2 dagger and then CS matrix and then R_1 direct some R_2 . This whole thing is called CS decomposition. Analyzing further this matrix, CS matrix and I will just write C_1, C_2 for cos theta 1, cos theta 2, S_1, S_2, S_1, S_2 here and C_1, C_2 and this can be written as identity I times identity, I times identity and identity. This is 2 by 2 identities.

(Refer slide time: 23:22)

$$U = (L_1^\dagger \otimes L_2^\dagger) (CS) R_1 \otimes R_2$$

CS Decomposition:

$$\begin{bmatrix} c_1 & s_1 \\ s_1 & c_1 \end{bmatrix} = \frac{1}{\sqrt{2}} \begin{bmatrix} 1 & 1 \\ -1 & 1 \end{bmatrix} \begin{bmatrix} e^{-i\theta_1} & 0 \\ 0 & e^{-i\theta_2} \end{bmatrix} \begin{bmatrix} 1 & -1 \\ 1 & 1 \end{bmatrix}$$

Beam Splitter (A, B)

BS

And then we have exponential of minus I theta 1, exponential of minus I theta 2, exponential of I theta 1, exponential of I theta 2. Identity minus I times identity, minus I times identity and identity. There is 1 over root 2 here and 1 over root 2 here. So we can decompose this CS matrix into a matrix without thetas and a phase matrix and matrix without thetas. What we have done here so far is we have decomposed this matrix of diagonals, this CS matrix into a matrix without any phase information theta and A matrix with diagonal matrix having the information about phases.

This matrix is a beam splitter acting only on the path information A and B irrespective of the polarization. It does not depend on polarization. Similarly, this matrix is the beam splitter matrix and it does not depend on the polarization state. But this is a phase matrix which gives you phase of theta 1 and theta 2 to horizontal and vertical polarizations in the two different paths. So the CS matrix can be represented as a beam splitter where the path A and path B are coming, then they merge and they go.

Here is the minus theta and this is the theta. This is a wave plate which will give us theta 1 and theta 2 phase width for horizontal and vertical polarizations. And here it will have minus sign in the phase and this will have plus sign. So, these two will give you the matrix, diagonal matrix of phasor. And then we have another beam splitter, beam splitter and beam splitter.

In this way, we can implement this cosine and sine matrix. So, now what is left is the R1 R2 L1 L2 matrices in this representation. R1 and R2 acts on the state first, then the diagonal matrices and then L1 L2 in the diagram, state goes from here, this is path a this is path b. So first we apply R1 and R2, then we have our CS matrix and then we apply L1 dagger and L2 dagger. In that way, we can implement an arbitrary four-dimensional unitary on polarization and power degree of freedom of a photon. Now, one can ask the question, how do we implement L1, L2, R1 and R2 matrices on the unitary on the

polarization? This can be achieved by using two half-wave plates and one quarter-wave plate or two quarter-wave plates and one half-wave plate.

(Refer slide time: 24:50)

That scheme is pretty well known and one can find it online. This L_1 , L_2 , R_1 , R_2 can be implemented easily using quarter wave plates and half wave plates and we are not going to discuss that in detail in this lecture. Now once we know that any arbitrary unitary can be implemented by decomposing it into actions on polarization and action on the paths alone. Then we consider our U which contains the information about the measurement operators K_0 and K_1 and arbitrary matrices U_{12} and U_{22} . By comparing this thing with the earlier discussion, we can see that K_0 is $L_1^\dagger D A$ or let me write $\cos \theta_1$, $\cos \theta_2$, R_1 and K_1 is $L_2^\dagger D A$, $\sin \theta_1$, $\sin \theta_2$, R_1 .

(Refer slide time: 27:51)

$$U = \begin{bmatrix} K_0 & U_{12} \\ K_1 & U_{22} \end{bmatrix}$$

$$K_0 = L_1^\dagger \begin{bmatrix} c_1 & 0 \\ 0 & c_2 \end{bmatrix} R_1$$

$$K_1 = L_2^\dagger \begin{bmatrix} s_1 & 0 \\ 0 & s_2 \end{bmatrix} R_1$$

SVD

$$c_1, c_2, L_1, L_2, R_1, R_2 = \mathbb{1}$$

$$\Rightarrow U_{12} = L_1^\dagger \begin{bmatrix} -c_1 & 0 \\ 0 & -c_2 \end{bmatrix}$$

$$U_{22} = L_2^\dagger \begin{bmatrix} c_1 & 0 \\ 0 & c_2 \end{bmatrix}$$

So, K_0 and K_1 are given to us, L_1 and R_1 are unitary matrices, L_2 and R_1 are unitary matrices and there is a diagonal matrix. So, this automatically becomes the singular value decomposition of matrix K_0 and K_1 . So, for a given K_0 , K_1 , we can always find L_1 , R_1

and C1, C2. Similarly, for K1, we can find L2, R1 and S1, S2. From here, we have information about theta 1, theta 2, L1, L2, R1 and R2 is unknown.

For simplicity, we can choose R1, R2 to be anything and we can choose it to be identity also. Identity is a valid unitary matrix. Then our U12 will become L1 dagger minus S1, sine 1 minus sine 2 sine theta 2 and times identity. So, identity we do not need to write and U22 becomes L2 dagger cos theta 1, cos theta 2, 0. So, in that way, by choosing R2 to be identity, we have made the choice of U12 and U22 to be easy.

It is no longer arbitrary. It is the simplest we can find in our setup. Maybe if we are using different scheme to implement the unitary, we can choose R2 to be different so that the U12 and U22 are more easy to implement. And the whole scheme will look like the following. There is R1 and this is path A. So, if the photon enters in the path A, then there is a beam splitter.

There is a phase theta, minus theta here and plus theta. So, I'm just writing theta but it contains theta 1 and theta 2 corresponding to h and v and this can be implemented with the wave plates there is another beam splitter and then we have L1 dagger L2 dagger and outcomes. So, we send the photon in this path. We perform the unitary U, which contains the information about K0 and K1, and after passing through all these things, the polarization state here will be proportional to K0 psi. And this is the psi state coming in. So, it is A tensor psi, and K0 psi and this will be K1 psi state coming in.

(Refer slide time: 29:30)

So, if we just detect the number of photons coming in the upper mode or the lower mode that will give us the probability P0 which is Psi k0 dagger k0 Psi and P1 which is Psi k1 dagger k1 Psi. So, in that way we can implement these two effects POVM when the measurement operators are given to us. We can generalize this scheme to any number of POVM elements in a set. So, in that way, this is very general scheme.
