Lecture - 40
Radial Growth of Droplets by Diffusion-Continued

Hello, dear students. So, we will continue our discussion to derive the Radial Growth of a Droplet, subject to the conditions that are existing in the ambience. So, we will take the diffusion to be the main process by which the droplet is growing in size right. So, we have stopped at this point, where we have derived an expression for the density change with respect to the density of the ambience at saturation in terms of temperature changes latent heat and the specific gas constant.

So, if you say that the diffusion is the main process, let us say associated with the condensation is the relation with the release of latent heat which rises the droplets temperature above the ambient value.

(Refer Slide Time: 01:22)

Associated with condensation is the release of latent heat which raises the droplet temperature above the ambient value. The diffusion of heat away from the droplet is given by

$$\frac{dQ}{dt} = 4\pi r K (T_r - T) \quad (7)$$

where T is the ambient temperature and T_r is the temperature at the surface of the droplet, and K is the coefficient of thermal conductivity of the air.

Condensation of water vapor releases heat (ml) and the rate of release is $l \frac{dm}{dt}$. The latent heat of condensation is transported by diffusion away from the droplet (assuming no changes in temperature with time - steady state). We can then derive the following equation:

$$\frac{dQ}{dt} = l \frac{dm}{dt} \quad (8)$$

$$\frac{\rho_v - \rho_{v,r}}{T_r - T} = \frac{K}{DL} \quad (9)$$

Handwritten notes on the right side of the slide: T_e to T_R , ambience, Radius (or) surface of droplet, $r_e \rightarrow r_R$.

Handwritten notes on the left side of the slide: $\frac{\rho_{ve} - \rho_{vr}}{T_R - T_e} = \frac{K}{LD}$

So, in the integration while we were identifying the limits of integration, we have seen that the integration is to be carried out from a temperature T_e to temperature T_R , where T_e is the temperature of ambience and T_R is the temperature at the radius or surface of the droplet.

So, why is the temperature different between these two places?, what is the physical process that is happening? In order to understand this. When the condensation happens release of latent heat is of course, is there when the condensation happens latent heat is released and this heat is attributed to the droplet which rises the temperature from let us say T_e to T_R above the ambient value.

So, the diffusion of the heat away from the droplet so, once there is a temperature gradient, once you say that the temperature of the droplet or the surface of the droplet is larger there is; obviously, a reason for this temperature to go away or for the energy to conduct. So, how does the energy the gradient in the temperature compensate itself by conduction, I mean the heat is given out.

So, the diffusion of heat away from this droplet is given by this. So, this is a simple conduction equation, where the rate of change of temperature of course, the rate at which heat is given out with respect to time is of course, something to do with the radius or the size of the droplet, the coefficient of thermal conductivity and the difference of the temperature. So, T_R is the temperature of the or the surface of the droplet capital T is the temperature of the ambient.

So, if this difference is 0 then there is no heat conducted of course, absolutely, but since there is a difference, why does the difference come in first place? Because it has to accommodate the latent heat that is released, when the condensation happens so, this is a simple conduction equation, where the T is the ambient temperature T_R is the temperature at the surface of the droplet capital K is the coefficient of thermal conductivity.

So, the condensation of water vapor it gives out a heat ml , ml is the amount of heat and the rate of release is $l \frac{dm}{dt}$. The rate at which this is released l is; obviously, not a function of time. So, we keep it out of the differential. So we say that $l \frac{dm}{dt}$ is the rate of change of release of the heat.

So, the latent heat of condensation is transported by diffusion away from the droplet. Assuming that the no changes in temperature with steady state, we can simply derive these two equations. So, this is of course, the rate of heat that is being conducted or being released from the droplet is $l \frac{dm}{dt}$

So, if you substitute this we can simply say that the density of the vapor minus the density of vapor at the radius by T_R minus T_e is the coefficient of thermal conductivity this is the coefficient of diffusion and this is the latent heat. So, in our terminology, we can write this as $\rho_v e$ minus $\rho_v R$ divided by T_R minus T_e is k by $L D$.

(Refer Slide Time: 04:49)

$$\frac{p_{R_s} - p_{e_s}}{p_{e_s}} = \left(\frac{T_R - T_e}{T_e} \right) \left[\frac{L}{R_v T_R} - 1 \right]$$

So, this is one equation, we are going to supplement with our earlier equation. So, let say this is equation number one from here. So, we call this as equation two. So, how many equations do we have now?

(Refer Slide Time: 05:02)

$$\frac{p_v - p_{vR}}{T_R - T_e} = \frac{k}{LD} \quad \text{--- (2)}$$

$$p_{vR} = \frac{e'(r)}{R_v r} \left[1 + \frac{a}{r} - \frac{b}{r^2} \right] \quad \text{--- (3)}$$

Annotations for Equation 3:
 - $e'(r)$: Curved
 - R_v : Specific gas constant
 - r : Temperature at the surface of droplet.

So, we have, for example, $\rho_v r - \rho_v R$ divided by $T_R - T_e$ is equal to k by LD . Again simply the ideal gas equation $\rho_v R$ is $e p_r$. Now, we are talking about a droplet right by $R V T r$ what is this? The density this is very important this of course, this is just ideal gas equation this is the density of vapor at the surface of the droplet. This is the curved at the curvature term involved here, this is the specific gas constant and T of course, is the temperature at the surface of droplet.

Now, so, here now we can involve. So, if this is with respect to the curvature, we have to use the (Refer Time: 06:26) relation or the curvature and the solute effect. So, we can write this expression as e_s of infinite to $1 + a$ by r minus b by r cube divided by $r v T r$ right. So, let us say this is equation 2 now and this is equation by the way this is $\rho_v r$ this is equation 3.

So, we have equation number 1 which is this equation 1, we have 2, we have 3 right. Now, from these 3 equations we will do some rearrangement of these 3 equation and we will try to see how we can derive an expression.

(Refer Slide Time: 07:28)

The slide contains the following handwritten equations:

$$\underline{T_R - T_e} = \frac{L}{4\pi k R} \frac{dM}{dt} \quad M: \text{mass of the droplet}$$

$$\frac{p_{vs} - p_{vm}}{p_{vm}} = \frac{LD}{KT} (p_{vs} - p_v) \left[\frac{L}{R_v T} - 1 \right]$$

$$\frac{p_{rs} - p_{es}}{p_{es}} = \left[\frac{L}{R_v T} - 1 \right] \frac{L}{4\pi k R} \frac{dM}{dt} \quad \text{--- (4)}$$

$$p_e - p_a = (4\pi D)^+ \frac{dM}{dt}$$

Dividing this p_{es}

$$\frac{p_e - p_s}{p_{es}} = \frac{dM}{dt} \cdot \frac{1}{4\pi p_{es} D} \quad \text{--- (5)}$$

So, we can say that $T_R - T_e$ is L by $4\pi k R$ into dm by dt . where M is the mass of the droplet. So, we can now combine these 3 equations as $\rho_v s - \rho_v r_s$ divided by $\rho_v r_s$ is equal to LD by KT to $\rho_v r$ minus ρ_v times L by $R_v T$ minus 1 or $\rho_v r_s - \rho_e s$ divided by $\rho_e s$ is equal to L by $R_v T r$ minus 1 times L by $4\pi k R T_e$ dM by dt . So, this is $T_R - T_e$ that, we have used in this expression. So, T_e is still remains the same. So, T_e is still here.

So, let us say this, we will now try to simplify this equation. Now, we know that ρ_e minus ρ_r is $\frac{4\pi D}{dm/dt}$ dividing this expression with ρ_{es} , we will get ρ_e minus ρ_r divided by ρ_{es} is equal to $\frac{dm}{dt} \times \frac{1}{4\pi \rho_{es} D}$. Let us say we call this equation as 4, in this order, what we call this equation as 4 and we call this equation as 5. So, this is 4 and this is 5.

(Refer Slide Time: 10:18)

Adding (4) & (5)

$$\text{addition of LHS} \Rightarrow \left(\frac{\rho_e - \rho_r}{\rho_{es}} \right) + \left(\frac{\rho_{rs} - \rho_{es}}{\rho_{es}} \right) = \frac{\rho_e - \rho_r + \rho_{rs} - \rho_{es}}{\rho_{es}} \Rightarrow$$

$$\text{let } \underline{\rho_r = \rho_{rs}}$$

$$\Rightarrow \frac{\rho_e - \rho_{es}}{\rho_{es}} = \left[\frac{\rho_e}{\rho_{es}} \right] - 1 = \underline{S - 1}$$

\downarrow
 (S) Saturation ratio
 S-1: Supersaturation ratio

Now, let us add equation number 4 and equation number 5. We will get on the left hand side ρ_e minus ρ_r divided by ρ_{es} plus ρ_{rs} minus ρ_{es} divided by ρ_{es} which is equivalent to ρ_e minus ρ_r plus ρ_{rs} minus ρ_{es} divided by ρ_{es} . So, let us say ρ_r is equal to ρ_{rs} ; that means, the density at the surface is equal to the density at saturation.

So, in this case this expression reduces to simply ρ_e minus ρ_{es} divided by ρ_{es} that is also equal to ρ_e divided by ρ_{es} minus 1. So, the vapor density of the ambience with respect to the density of saturation can be defined to be equal to S minus 1. So, this term is equal to S. What is S? S is the saturation ratio and S the maximum value that the saturation ratio is expected to possess is ideally equal to 1. So, the quantity S minus 1 is of course, indicates the super saturation. So, you have already. So, S is the saturation ratio which is 1 ratio if it is the ratio its 1 or if it is saturation its 100 percent.

Now, this term itself can be maximum 100 and you take a 100 out of it I mean 1 out of it. Then you will realize, what is this super saturation ratio. So, now, this was the addition of LHS alone.

(Refer Slide Time: 12:50)

Adding the RHS of (4) & (5)

$$\frac{1}{4\pi\rho_{es}D} \left(\frac{dM}{dt}\right) + \left(\frac{L}{R_v T R} - 1\right) \frac{L}{4\pi R K} \frac{dM}{dt} = S - 1$$

$$\frac{dM}{dt} \left[\left(\frac{L}{R_v T R} - 1\right) \frac{L}{4\pi R K T_e} + \frac{1}{4\pi R D \rho_{es}} \right] = S - 1$$

$$\frac{dM}{dt} = \frac{4\pi R (S-1)}{\left(\frac{L}{R_v T R} - 1\right) \left(\frac{L}{K T_e}\right) + \frac{1}{D \rho_{es}}}$$

M: Mass of droplet

$$M = \frac{4}{3} \pi R^3 \rho_L \Rightarrow \frac{dM}{dt} = \rho_L 4\pi R^2 \frac{dR}{dt}$$

Now, let us adding the RHS of equation number 4 and equation number 5. We will realize 1 by 4 pi rho es capital D times dm over dt plus L by Rv TR minus 1 times L by 4 pi R k dm by dt. Now it is equal to S minus 1, we have already done this.

So, take d m over dt outside then, we will realize L by R v T r minus 1 to L by 4 pi R K T e plus 1 by 4 pi RD rho e s S minus 1 or dm by dt is equals to four pi R into S minus 1 divided by L by Rv T R minus 1 into L by K T e plus 1 by D rho es.

So, what is M? M is the mass of droplet. So, M can be written as 4 by 3 pi R cube times the density of the liquid, mass is density times volume. So, this is the volume of the droplet, mass of the droplet and the density which is of course, the density of the liquid.

So, if you write similarly dM over dt ,the rate of change of mass with respect to temperature. So, what should it depend on is the density of course, which remains a constant and of course, 4 pi R square into d R over dt. So, rate of change of mass will only depend on the rate of change of the radius, the remaining are constants.

So, we will have to substitute this, I mean the point of making that taking this derivative is to be able to substitute this into this.

(Refer Slide Time: 16:18)

$$p_{es} = \frac{\rho_{es}}{R_v T_e}$$

$$R^2 \frac{dR}{dt} \cdot \cancel{p_{es}} = \frac{\cancel{4\pi R} (S-1)}{\left(\frac{L}{R_v T_R} - 1\right) \left(\frac{L}{k T_e}\right) + \frac{1}{D \rho_{es}}}$$

$$R \frac{dR}{dt} = \frac{S-1}{\left(\frac{L}{R_v T_R} - 1\right) \left(\frac{L \rho_L}{k T_e}\right) + \rho_L R_v \left(\frac{dR}{dt}\right)}$$

So, let us say we know that from the ideal gas equation $\rho_{es} = p_{es} / (R_v T_e)$ what is ρ_{es} ? ρ_{es} is the density of water vapor at saturation, is equal to the vapor pressure at saturation divided by $R_v T_e$ just the ideal gas law.

So, let us say, we use this density change R , where is it $R^2 dR/dt$ into ρ_L times 4π yeah 4π is equals to $4\pi R$ times the super saturation ratio divided by L by $R_v T_R$ minus 1 into L by $k T_e$ plus 1 by $D \rho_{es}$. If you cancel this simply be able to write $R dR/dt$ is $S - 1$ to L by $R_v T_R$ minus 1 to $L \rho_L$ divided by $k T_e$ plus $\rho_L R_v dR/dt$.

(Refer Slide Time: 18:16)

$$k \frac{dR}{dt} = \frac{S-1}{\left[\frac{L}{\rho_v R} - 1 \right] \left[\frac{L \rho_v}{k T_e} \right] + \left[\frac{L \rho_v T_e}{D e_s} \right]}$$

$$R \frac{dR}{dt} = \frac{S-1}{F_k + F_d}$$

F_k : Thermodynamic term (associated with heat)
 F_d : Vapor diffusion term

Or we can write it as $R \frac{dR}{dt}$ is equal to $S - 1$ divided by $\frac{L}{\rho_v R} - 1$ multiplied by $\frac{L \rho_v}{k T_e}$ plus $\frac{L \rho_v T_e}{D e_s}$. This is just simple algebra, I am just trying to rearrange the terms for the sake of convenience right. So, it should not be any worry if you do not understand you just have to look at the previous slides get all the equations together and rearrange them or substitute according with the method that we have followed you will be able to get it.

So, this we are going to call it as $R \frac{dR}{dt}$. So, first in simple terms, we are going to call it as $\frac{dR}{dt}$ is $S - 1$ divided by $F_k + F_d$. So, what is this F_k ? So, this is just a notation. So, this entire term is F_k and this term is F_d . So, what is F_k , why do we call it as F_k ? So, F_k is the thermodynamic term associated with heat and F_d is the vapor diffusion term. So, this term is associated with the diffusion and this term is associated with the thermal term.

(Refer Slide Time: 20:16)

$$R \frac{dR}{dt} = \frac{(S-1) - \frac{a}{R} + \frac{b}{R^3}}{(F_k + F_d)}$$

when R becomes sufficiently large, $\frac{a}{R}$, $\frac{b}{R^3}$ will be negligible

$$R(t) = \sqrt{r_0^2 + 2Ct}$$

$$C = \frac{S-1}{F_k + F_d}$$

Now, at this point again, we can introduce the solute and the curvature effects as $R \frac{dR}{dt}$ is equal to S minus 1 minus a by R plus b by R cube divided by F_k plus F_d . So, this is the generalized expression for the growth of a droplet how does it change with respect to time.

So, we have all the constants all the variables that will tell you what is the concentration of liquid, what is the concentration of ambience, what is the density because of the ambient vapor, what is the gas constant, what is the temperature everything every parameter is given here which will characterize or which will tell you the characteristics of the vapor and the droplet.

Now, given this so, we can find how the radius of a droplet changes over time that is the basic idea. Now, let us say if this is the case then when the radius R becomes sufficiently large. Then, we can simply say that a by R and b by R cube will be negligible. So, in that case we can reduce this expression as R of t , I mean we are going to integrate this and R a function of t will simply be r_0^2 the initial radius plus $2Ct$ where the constant C is S minus 1 divided by F_k plus F_d .

So, this is the expression which tells you how the radius of the droplet changes with respect to time. So, what we have seen is just to recap, if you see the mathematical treatment. So, far for us to understand or appreciate the expression. what we have done is we have simply taken the Clausius Clapeyron equation with the vapor and the liquid variables.

Then we have rearranged it in terms of density getting rid of the α . Where we saw that first time how the vapor pressure at saturation changes with respect to temperature, we will depend on the density at saturation and the temperature and the latent heat. Then, we wrote the vapor pressure at saturation in terms of the ideal gas law and we took its derivative and we equated the first two terms and then we got this equation.

After thus we take an integration of this resulting equation from the ambient temperature to the temperature of the droplet. then we got this expression then, we made a simple approximation when z is very very small, very small values of $z \log z + 1 + z$ is equal to eventually equal to z not $1 + z$ or not something it is just.

So, we applied this approximation on this parameter this ratio, then we derived how the density changes between the saturation between the radius between the surface and the ambience in comparison to the ambience. So, then we got this expression right, then we introduced the variables of thermal conductivity and the coefficient of diffusion saying that the diffusion is happening at the droplet surface and this diffusion the rate at which the diffusion is happening the rate at which the molecules are getting attached to the droplets must release some latent heat.

And, this heat must be must build up a gradient by allowing a heat conduction to happen from the surface of the droplet to the ambience. So, we took all these parameters and we later introduced the solute and the curvature effects into this. And then; we thought the mass has the droplet to be M and we try to find out the rate at which the mass of this droplet will change with respect to time. So, that is where the time dependence actually came into the picture.

So, we took the mass to be equal into density times volume, we took a derivative of the mass and that is where actually the time dependence has come into the picture otherwise that there is no time dependence so far in the picture. So, eventually we algebraically simplified all this things and then, we realized the rate at which the radius of the droplet changes is equal to simply these two terms $S - 1$ is the super saturation ratio divided by $F_k + F_d$, where F_k is the thermo dynamical term F_d is the diffusion term.

So, this concludes the discussion about the diffusional growth of a cloud droplet how it changes how its radius changes with respect to time. So, we will stop here. I suppose you can understand this.
