

# Advanced Digital Signal Processing – Wavelets and Multirate

Prof. V.M. Gadre

Department of Electrical Engineering

Indian Institute of Technology, Bombay

Module No. #01

Lecture - 11

## Two Channel Filter Bank

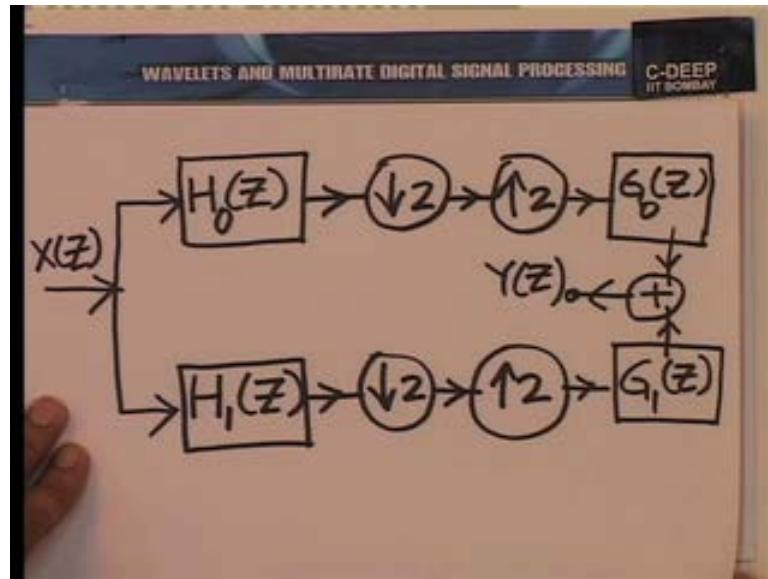

A warm welcome to the 11 th lecture on the subject of wavelets and multirate digital signal processing, in which we proceed further on the theme of the two-channel filter bank. You will recall that in the previous lecture the 10 th lecture, we had looked at what happens when a sequence process a down sampler and an up sampler. I would like to put before you the effect in the Z domain once again when we cross a down sampler and when we cross an up sampler.

(Refer Slide Time: 01:12)

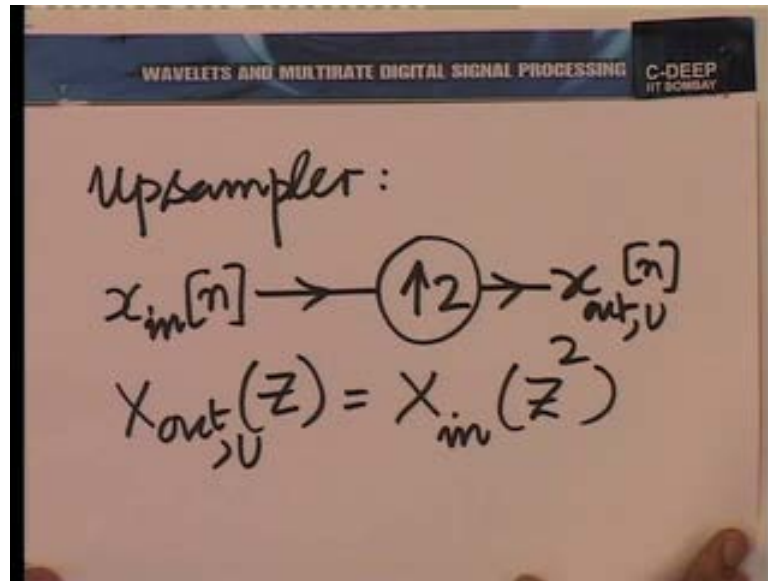

Today's lecture as I said is entitled the two-channel filter bank.

(Refer Slide Time: 01:31)

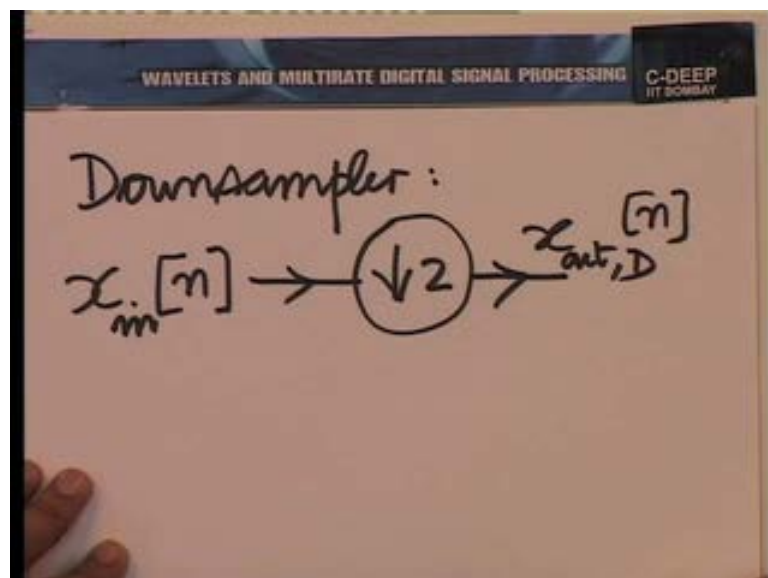

And we intend in this lecture to talk about this structure, which we been repeating often again, but today we intend to analyze it thread bear so to speak. Now remember, that  $H_0$  was a low pass filter,  $H_1$  a high pass filter you know it is helpful to get this structure firmly embedded in our consciousness. It is a structure often used in the implementation of a discrete wavelet transform, for example of the Haarmulti resolution analysis. So, it does no harm to repeat the structure more than once, we have been looking at the structure almost in every one of the last 2 to 3 lectures, but no harm done. Anyway, here is the structure once again and what we intend to do finally today in this structure is to relate the z-transforms at every point in this structure.

(Refer Slide Time: 03:25)

Let us start doing that and to do that let us first recall what happens when we go past a down sampler and up sampler. So as I said let us look at the up sampler first recall from the previous lecture. Note it from the previous lecture that, if you have  $X_{in}[n]$  going to an up sampler by a factor of 2 to produce  $x_{out,U}[n]$  here, then  $X_{out,U}(z)$  in this case may be to be specific we could say  $x_{out,U}$  to denote up sampling here, so  $X_{out,U}(z)$  is  $X_{in}(z^2)$  in this case. Let us similarly see, what happens when we go past a down sampler.

(Refer Slide Time: 04:25)

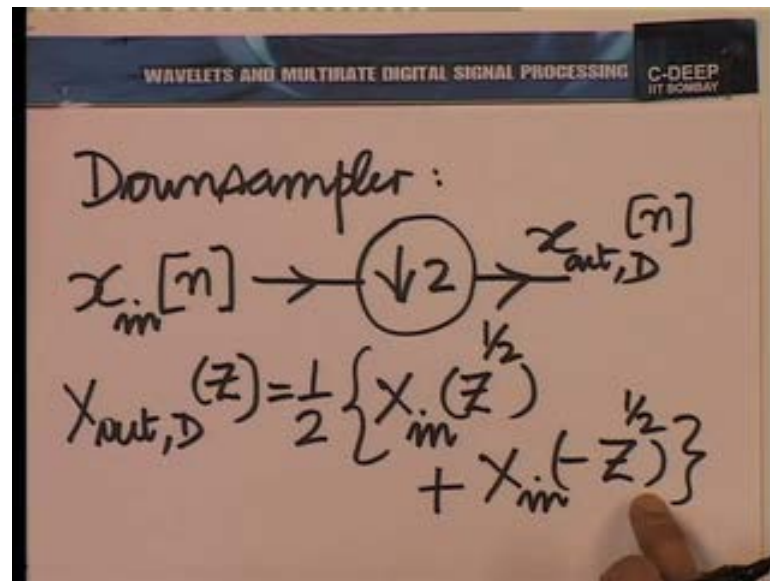

For the down sampler by a factor of 2, remember we had analyzed in detail the case of a down sampling by a factor of 2. We had indicated how to generalize, but it was a little more complicated so, here we have  $X$  out  $D_n$  if you please. And in fact, we had noted that this operation of down sampling by 2 was equivalent to 2 operations and let me spell out those operations once again following which I shall write down the z-transform here.

(Refer Slide Time: 05:22)

So, we had agreed that this operation of down sampling by 2 can be split into modulation with half 1 raise the power of n plus minus 1 raise the power of n first, followed by inverse up sampling by 2 inverse. We had noted that up sampling by 2 or up sampling by any integer factor for that matter was an invertible operation and in fact this is also evident in the Z domain and therefore, we can talk about the inverse here. Now, based on this we have written down the z-transform.

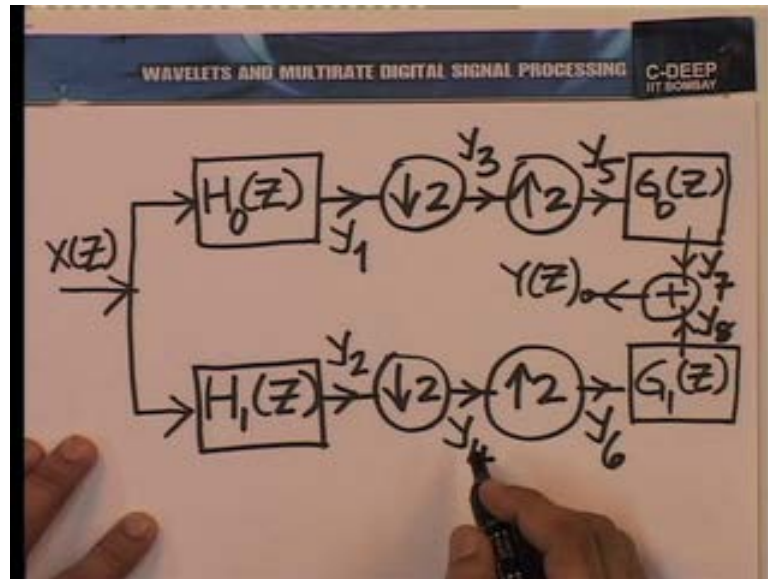

(Refer Slide Time: 06:30)

So, we have said  $X_{out,D}(z)$  here is half  $X_{in}(z)$  raise to the half plus  $x_{in}$  minus  $Z$  raise to the half, we have derived this towards the end of the previous lecture. And of course, if you did not wish to go beyond the inverse up sampler at this point instead of  $Z$  raise the power half you would simply have  $Z$  so much so then for the  $Z$  domain effect of downsampling and upsampling. Now, what do we intent to do next, We intent to use these relationships to buildup the relation between the  $z$ -transform of the output and the  $z$ -transform of the input. So, essentially we wish to establish the input output relationship in this two-band or two-channel filter bank in the  $Z$  domain.

Of course, I must make a remark here before we embark upon this activity. We are assuming that the  $z$ -transform exist at all points, there are rare situations or may be not so rare where that may not be true, but for the moment we shall ignore those situations. They are not very frequent in practical applications and therefore, we can comfortably begin with assumption that the  $z$ -transforms exist at all points. Of course, I do not mean the Fourier transform exist they may or may not. Anyway coming back then to that two-channel filter bank that it began with earlier on this lecture, I put it back before you here.

(Refer Slide Time: 08:30)

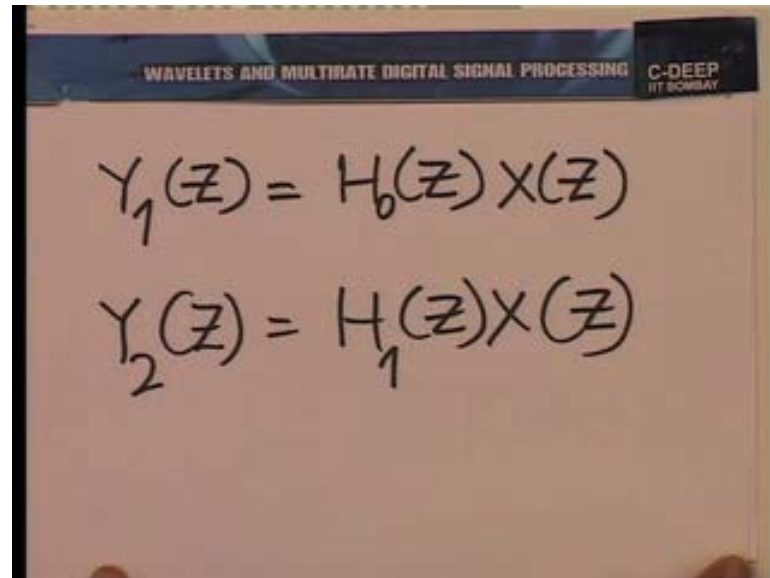

I intent now to relate  $Y(z)$  and  $X(z)$  in this diagram and towards at objective, let us number the  $z$ -transform at different points, in fact let us give the sequences names. So, Let us call this  $Y_1$  and let us call this  $Y_2$  and so on. And the varied output we shall just call  $Y$  without any substitute so, accordingly this becomes  $Y_3$  this  $Y_4$ , this  $Y_5$ ,  $Y_6$ ,  $Y_7$ ,  $Y_8$ , and then of course  $Y_9$  is simply  $Y$ . So, with this then let me write down the expressions for each of these, so let us begin with  $Y_1$ ,  $Y_1$  is easy and so is  $Y_2$ . In fact if we look at the  $Z$  domain relationships  $Y_1(z)$  is simply  $X(z)$  times  $H_0(z)$  and similarly,  $Y_2(z)$  is simply  $X(z)$  times  $H_1(z)$ . When we filter with a filter of system function  $H_0(z)$ , the effect is to multiply the  $z$ -transform of the input by the system function of the filter to produce the  $z$ -transform of the output.

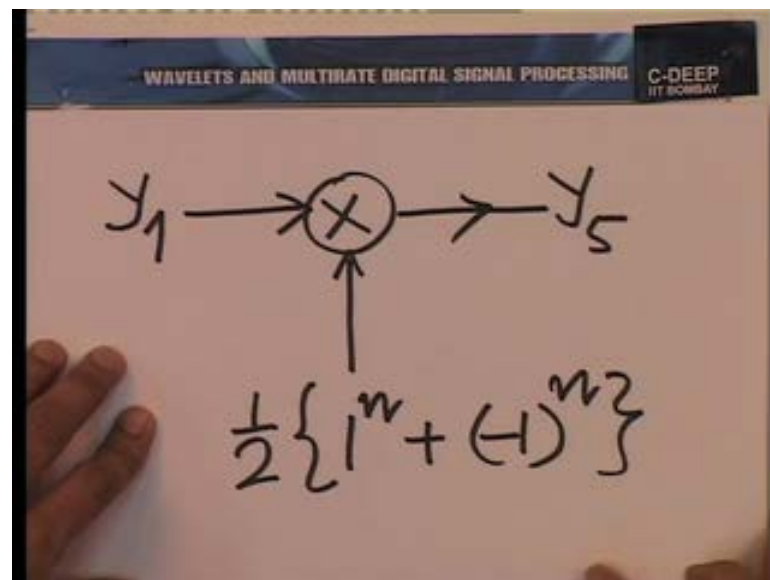

And therefore,  $Y_1(z)$  and  $Y_2(z)$  are easy.  $Y_1(z)$  is  $H_0(z)X(z)$ ,  $Y_2(z)$  is  $H_1(z)X(z)$ . Now we have before us, the relationship that emerges between  $Y_3$  and  $Y_1$  and similarly between  $Y_4$  and  $Y_2$ . As I said, downsampling by 2 is equivalent to a modulation and then and inverse upsampling by 2, it is easy then to jump from  $Y_1$  to  $Y_5$  first and  $Y_2$  to  $Y_6$ . Because if you think of this downsampling by 2 operation as a modulation followed by an inverse upsample by 2, the inverse upsample by 2 cancels with this upsample by 2, leaving only the modulation here. So, this is a strategy which we might find useful in some circumstances in analyzing multirate systems, particularly when we have a down sampler followed by an up sampler. You know, if you have a down sampler followed by

an up sampler of the same factor, it is some time easier to go past both of them and then jump back behind the up sampler, we will do exactly that here.

(Refer Slide Time: 10:30)

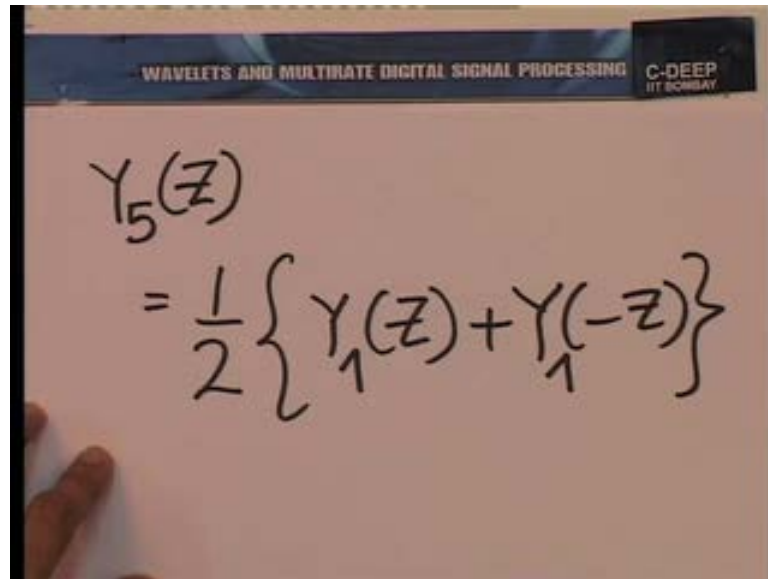

$$Y_1(z) = H_0(z)X(z)$$
$$Y_2(z) = H_1(z)X(z)$$

(Refer Slide Time: 12:30)

We will put the relation between  $Y_1$  and  $Y_5$  and  $Y_1$  to  $Y_5$  is essentially just a modulation, modulation by  $1$  raise the power of  $n$  plus minus  $1$  raise the power of  $n$  multiplied by half. And therefore, the  $z$ -transforms are easily related.

(Refer Slide Time: 13:08)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP IIT BOMBAY

$$Y_5(Z) = \frac{1}{2} \{ Y_1(Z) + Y_1(-Z) \}$$

$Y_5(Z)$  is half  $Y_1(Z)$  plus  $Y_1(-Z)$  and there is a very similar relationships between  $Y_2$  and  $Y_6$ , put this back  $Y_2$  and  $Y_6$  are related by the same modulation.

(Refer Slide Time: 13:50)

Let us write that down too. So, we have  $Y_2$  is modulated to obtain  $Y_6$ .

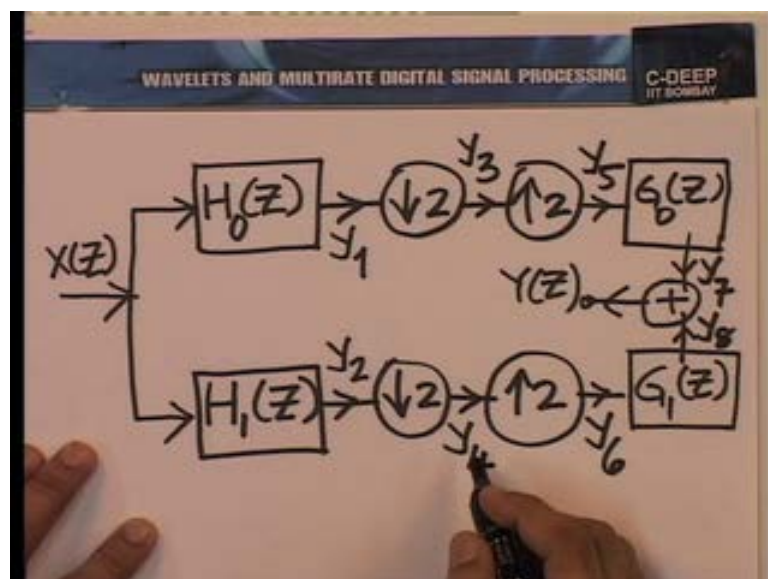

(Refer Slide Time: 14:19)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP IIT BOMBAY

$$Y_6(z) = \frac{1}{2} \left\{ Y_2(z) + Y_2(-z) \right\}$$

And therefore,  $Y_6(z)$  is half  $Y_2(z)$  plus  $Y_2(-z)$ . In fact, this jumping across the down sampler and the up sampler was useful, because it brought us quickly towards the output. Now, we are only almost one step away from the output, that step is also not very difficult to take. We just have two filters followed by a sum up, which is easy to do in the  $Z$  domain, so let us complete that exercise.

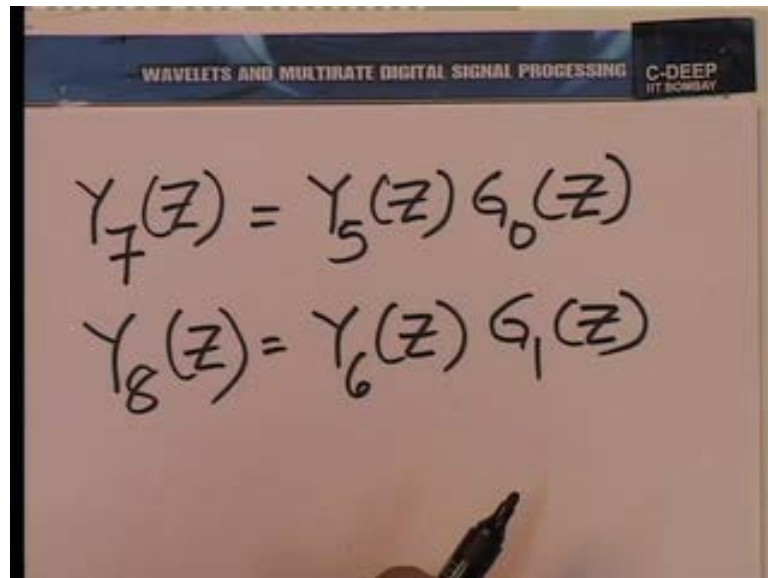

(Refer Slide Time: 08:50)

Now, we are here, we know what  $Y_5(z)$  is we know what  $Y_6(z)$  is.  $Y_5(z)$  is acted upon by a filter with system function  $G_0$  and therefore, the  $z$ -transform at the output here after  $G$

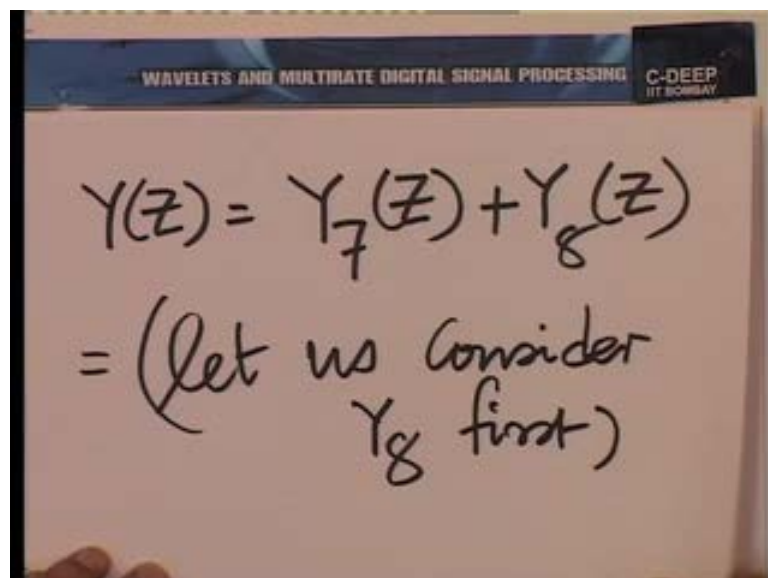

0 is the z-transform of  $Y_5$  multiplied by  $G_0$ . Similarly, the z-transform at the output of  $G_1$  is  $Y_6 Z$  multiplied by  $G_1 Z$  and in fact let me take you one step even further, after all  $Y Z$  is obtain by adding  $Y_7 Z$  and  $Y_8 Z$ . And therefore, we already have  $Y Z$  before us; let me write down those steps quickly before you now.

(Refer Slide Time: 16:10)

$$Y_7(z) = Y_5(z) G_0(z)$$
$$Y_8(z) = Y_6(z) G_1(z)$$

So, we have  $Y_7 Z$  is  $Y_5 Z$  times  $G_0 Z$  and  $Y_8 Z$  is  $Y_6 Z$  times  $G_1 Z$ .

(Refer Slide Time: 16:48)

$$Y(z) = Y_7(z) + Y_8(z)$$

= (let us consider  $Y_8$  first)

Where upon  $Y Z$  which is  $Y_7 Z$  plus  $Y_8 Z$  becomes let me put before you the expression for  $Y_5$  and  $Y_6$  once again so, let us take  $Y_6$  as an example. Now you are

going to involve  $Y_2(z)$  and  $Y_2(-z)$ ,  $Y_2(z)$  if you recall is  $X(z)$  times  $H_1(z)$  as an example. Now, when you take  $Y_2(-z)$ , you would get  $X(-z)$  multiplied by  $H_1(-z)$ , in fact let me put that down. What I am trying to do is to identify a form of the expression so; this  $Y_2(-z)$  has two terms embedded in it.

(Refer Slide Time: 18:22)

The slide shows two equations written in black ink on a light brown background. The top equation is  $Y_8(z) = Y_6(z)G_1(z)$ . The bottom equation is  $Y_6(z) = \frac{1}{2} \left\{ Y_2(z) + Y_2(-z) \right\}$ .

So, let us focus, let says for example, on this term here  $Y_8$ .

So,  $Y_8(z)$  as I said is going to be  $Y_6(z)$  times  $G_1(z)$ .  $Y_6(z)$  is going to be related to  $Y_2(z)$ .

(Refer Slide Time: 19:01)

The slide shows two equations written in black ink on a light brown background. The top equation is  $Y_2(z) = X(z)H_1(z)$ . The bottom equation is  $Y_2(-z) = X(-z)H_1(-z)$ .

And then  $Y(z)$  is further going to be  $X(z)$  times  $H_0(z)$  where upon  $Y(-z)$  is going to be  $X(-z)$  times  $H_1(-z)$ . What I am trying to bring out from this argument or these equations is that each of these terms is going to have a contribution from  $X(z)$  and a contribution from  $X(-z)$ . Now later on, we shall interpret these terms  $X(z)$  and  $X(-z)$ , but for the time being all that we need to do is to identify that there is  $X(z)$  set of terms and  $X(-z)$  set of terms, which we can together write down as follows.

(Refer Slide Time: 20:11)

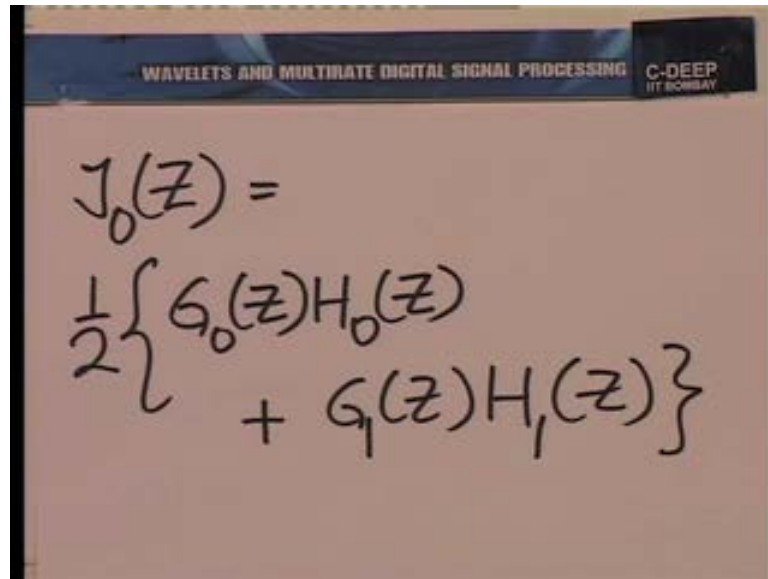

The image shows a whiteboard with the following handwritten text:

In total

$$Y(z) = \underbrace{T_0(z)} X(z) + \underbrace{T_1(z)} X(-z)$$

We will say  $Y(z)$  in total is of the following form. It is going to have some system function multiplying  $X(z)$  and some other system function multiplying  $X(-z)$  and using all the equations within so for we can write down these two system functions, call them  $T_0(z)$  and  $T_1(z)$ .

(Refer Slide Time: 20:43)

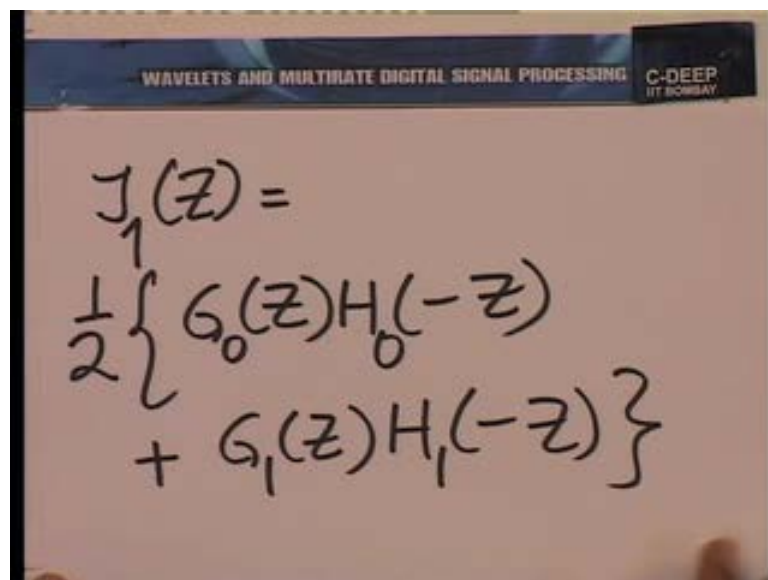

The slide shows the following handwritten equation:

$$J_0(z) = \frac{1}{2} \left\{ G_0(z)H_0(z) + G_1(z)H_1(z) \right\}$$

Indeed  $J_0(z)$  has the following form.

It is it is require a little bit of algebra to get here, I would not actually do all the steps I am sure all of you can do them and now, we write  $J_1(z)$  as well.

(Refer Slide Time: 21:19)

The slide shows the following handwritten equation:

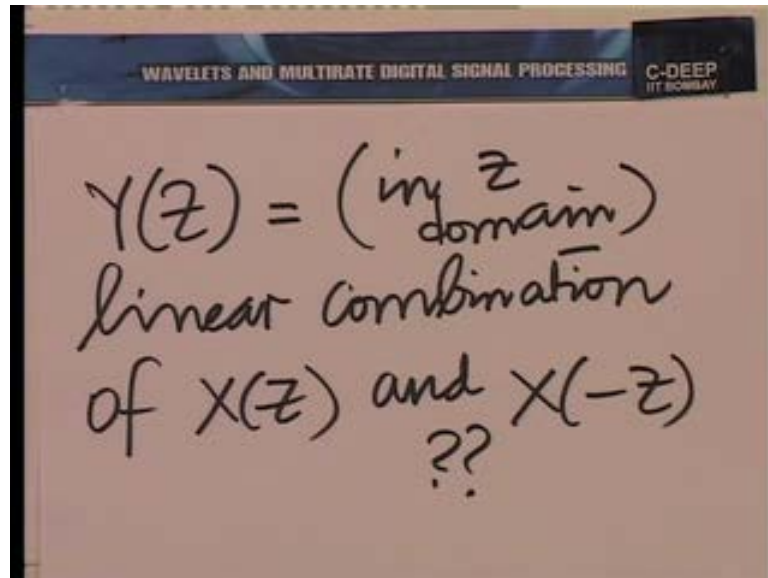

$$J_1(z) = \frac{1}{2} \left\{ G_0(z)H_0(-z) + G_1(z)H_1(-z) \right\}$$

So,  $J_1(z)$  would be...

$G_0(z)H_0(-z) + G_1(z)H_1(-z)$ . Now, it should be noted that in  $J_1(z)$  which is what multiplies  $X(-z)$ , you involve  $H_0(-z)$  and  $H_1(-z)$ .

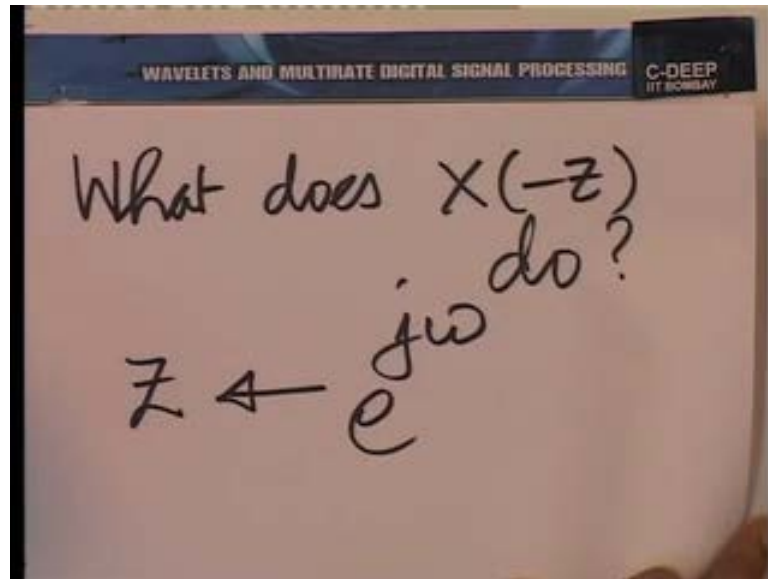

So, you never involve  $G_0$  minus  $Z$  or  $G_1$  minus  $Z$ , the  $Z$  replacement by minus  $Z$  is only for the analysis side.

(Refer Slide Time: 22:22)

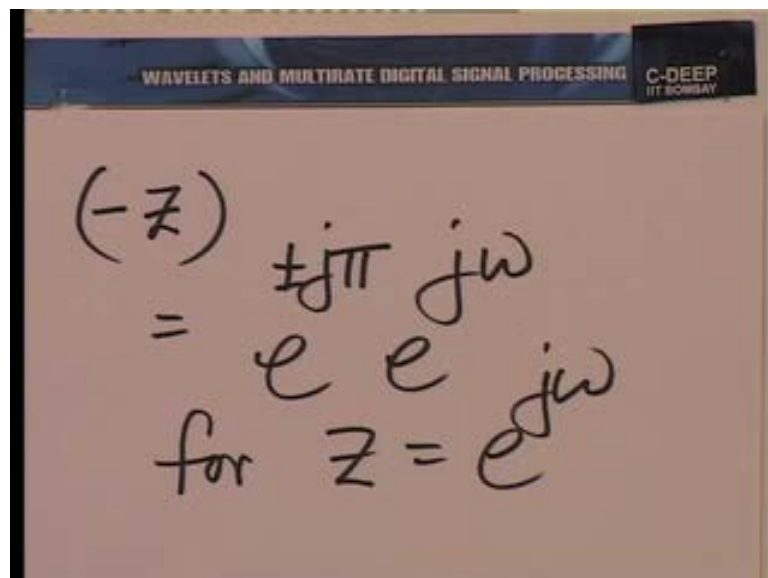

Anyway with this little observation, we now write down  $Y(z)$  once again for clarity. So,  $Y(z)$  is a linear combination, I mean in the  $z$  domain of  $X(z)$  and  $X(-z)$ . What is this mean, what you mean linearly combining  $X(z)$  and  $X(-z)$ ? If the  $X(-z)$  term were not to be there, then we have a simple expression there.  $Y(z)$  is some function in  $z$  multiplied  $X(z)$  that is, the good old linear shift invariance system for you with a system function. And in this case if  $\tau_1(z)$  were to be absent, the system function would be simply  $\tau_0(z)$ ,  $\tau_1(z)$  is the troublemaker here. And we need to understand first what this  $X(-z)$  is? What does it do spectrally? What does it do in the time domain? So, let us understand that now.

(Refer Slide Time: 23:45)

What does  $X(-z)$  do? And to answer to this question, we put  $Z$  equal to  $e^{j\omega}$  as we always do to interpret things in the frequency domain.

(Refer Slide Time: 24:17)

Now when you replace  $Z$  by  $-z$ , you are replacing  $e^{j\omega}$  by  $e^{j\pi} e^{j\omega}$ . We call that  $e^{j\pi}$  is  $-1$  so, now we have an interpretation for multiplication by  $-1$  in the  $Z$  domain.

(Refer Slide Time: 24:50)

Essentially, we are replacing  $e^{j\omega}$  by  $e^{j(\omega \pm \pi)}$ . In other words, we are shifting on the  $\omega$  axis by either  $\pi$  or  $-\pi$ . Now, it should be noted that shifting by  $\pi$  and shifting by  $-\pi$  are the same thing, that is because there is periodicity on these small  $\omega$  on the normalized angular frequency axis, a periodicity with a period of  $2\pi$ . So, there is no problem, if we replace plus  $\pi$  by minus  $\pi$  there, shifting by plus  $\pi$  and shifting by minus  $\pi$  are the same thing. With that little remark in observation, what we have done in replacing  $Z$  by  $-Z$  as far as the normalized angular frequency is concerned is to shift by  $\pi$ , whether plus  $\pi$  or minus  $\pi$ . And we would best understand what the shift implies if we took an example spectrum.

(Refer Slide Time: 26:11)

So, let us take an example spectrum to complete this discussion. Let us take this spectrum, consider an idealized spectrum like this essentially with lines, line between minus pi by 2 and plus pi by 2 and 0 outside. So, this is the spectrum of some sequence, let that sequence be  $X$  of  $n$  so, this is the normalized angular frequency  $\omega$ . This is capital  $X$  of strictly  $e$  raise the power  $j \omega$ . But as you know in discrete time processing, we sometimes abused notation a little bit and we write just  $X(\omega)$  instead of  $X(e^{j\omega})$ , which is more correct. But anyway I must emphasize that as far as we are concerned from the context capital  $X(\omega)$  and capital  $X(e^{j\omega})$  essentially mean the same thing. Now with that remark, what happens when you shift by  $\pi$  here?

(Refer Slide Time: 27:49)

So, recall that actually this is what  $x$  raised to the power  $j\omega$  is so, we will do a bit of zone here.

Periodically repeat it with a period of  $2\pi$ , this is what  $x$  of the  $e$  raised to the power  $j\omega$  actually is. So, you can visualize if you shift this either forward or backward by  $\pi$ , it is going to give you the same thing and what is going to appear after shifting by  $\pi$  is the following.

(Refer Slide Time: 29:17)

Would therefore, appear like this. Again, we shall do a bit of zooming here and so on here and so on there. So, now here triangles are around  $\pi$  and then  $3\pi$  and so on and here around minus  $\pi$  and then minus  $3\pi$  and so on. So, now again if you take the principle interval which is here, this is what we get.

(Refer Slide Time: 30:46)

We know must be a little more explicit in our relationships. So, in  $x$  of  $e$  is the power  $j$   $\omega$ , if you look at principle interval minus  $\pi$  to plus  $\pi$ , we notice there are two segments here for the positive side of the  $\omega$  axis and the negative side of the  $\omega$  axis. Let us call the segment for the positive side  $A$  and the segment for the negative side  $A$  bar and in fact there is a reason for this. Remember, that the discrete time Fourier transform has conjugate symmetry for a real sequence. So, it is with that reminiscence that we are writing  $A$  and  $A$  bar, I agree that if the sequence is complex this conjugate symmetry would not be there. But very often we deal with real sequences and therefore, it is useful to put the symbols  $A$  and  $A$  bar there just for emphasis. Anyway, now what we will do is, in  $x$  of  $e$  raise the power  $j$   $\omega$  plus minus  $\pi$ , we shall mark the  $A$ 's and the  $A$  bar's carefully.

(Refer Slide Time: 31:52)

So, here again in the principle interval, this was actually A and this was A bar, is it not. And therefore, this was A and this A bar and now what we need to do is to expand the principle interval for our convenience.

(Refer Slide Time: 32:28)

So, expanding the principle interval, this is what we get.

We getting an A bar here and we get an A there. You know, Just for convenience I shall show in dotted on the same diagram what we had just for capital X. So, what I am saying is the solid lines here are X omega plus minus pi and I shall show in dotted X omega just

to be clear. Again for give the abuse ((.)) of notation where we replaced  $e^{j\omega}$  by just  $\omega$  for clarity here all right. So, you know in  $X(\omega)$  you had  $A$  here and  $A^*$  there and now you have  $A^*$  here and  $A$  there. So, what has happened is an effect, this so call negative frequencies between  $-\pi/2$  and  $0$  have now appear between  $\pi/2$  and  $\pi$  so, two things have happened, the order of the frequencies has been reversed.

For example, in principle a frequency let us say  $-\pi/4$  here is more than a frequency of let us say  $-\pi/8$  here you would have  $0, \pi/8, \pi/4, 3\pi/8$  and so on and the same on this side. So, if you take a  $-\pi/8$  frequency here and then  $-\pi/4$  frequency there, the  $-\pi/4$  frequency appears as a smaller frequency here. One can see that, because the order of frequencies from  $0$  to  $\pi$  or  $0$  to  $-\pi/2$  has been now reorder between  $\pi$  and  $\pi/2$ . So, increasing magnitude of frequency here becomes decreasing magnitude of frequency there, secondly, the frequencies themselves change. So you know, actually this is exactly what happens in what is called aliasing, many of us will recall from theory of sampling and aliasing this is something very fundamental.

In a course on discrete time signal processing or in the process of sampling a continuous time signal to get discrete sequence these things happen. So, if we do not sample at an adequate rate, we get a problem called aliasing. What is aliasing? Aliasing is a phenomenon where a sine wave assumes a false identity and there are two things that happens in aliasing. One of them is of course, that the frequency of the sine wave appears to change. The other is that when you increase the frequency of the sine wave, the apparent sine wave or the sine wave produced by impersonation if you would like to call it that seems to have its frequency reducing so, an increasing frequency and increasing actual frequency seems to appears as an apparently reducing frequency.

These two things together compromise ((.)) together make up the concept of aliasing and what we are seeing here is just an instant of aliasing. Why are we seeing aliasing? It is not very difficult to understand, what we have done is to downsample? You know, in the process of downsampling, we in fact introduce the possibility of aliasing and this  $X(\omega - Z)$  term is bringing before you the consequences that would be there if aliasing where allowed to remain think about it.  $X(\omega - Z)$  is therefore, called the aliasing term, because it tells you the contribution of possible aliasing. In the two band perfect three

construction filter bank, which we shall soon see, this aliasing should be absent by a perfect reconstruction.

I mean, if  $Y$  is to be an exact replica of  $X$  as is the case for example, in the Haar system when you chosen the filters properly. So, you analyze or you decompose and then you synthesis or reconstruct and if the reconstruction is perfect, there should be no realize. So the  $X$  (minus  $Z$ ) term is a trouble maker term in general, trouble maker in this sense. Let us make a note of this.

(Refer Slide Time: 38:57)

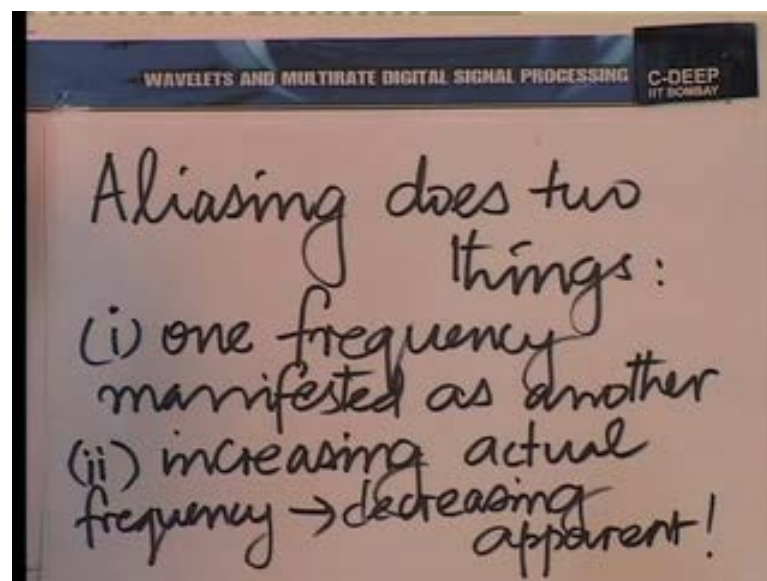

So, the  $X$  (minus  $Z$ ) term or equivalently, the  $X$  (minus  $e$  raise the power  $j$   $\omega$ ). Or  $X$   $e$  raise the power  $j$   $\omega$  plus minus  $\pi$  term is the consequence of aliasing. What is the consequence of aliasing, we should put it down very clearly. Aliasing does two things, one; frequency manifested as another, two; increasing actual frequency leads to decreasing apparent frequency. So, in fact just to emphasis, let me put back before you and stress this point, as you increase the frequency from  $0$  to  $\pi$  by  $2$  here, the frequency appears to decrease from  $\pi$  to  $\pi$  by  $2$  there. The first thing we have to do if you want perfect reconstruction is to do away with aliasing so, you put down a condition for aliasing cancellation.

(Refer Slide Time: 39:19)

(Refer Slide Time: 39:51)

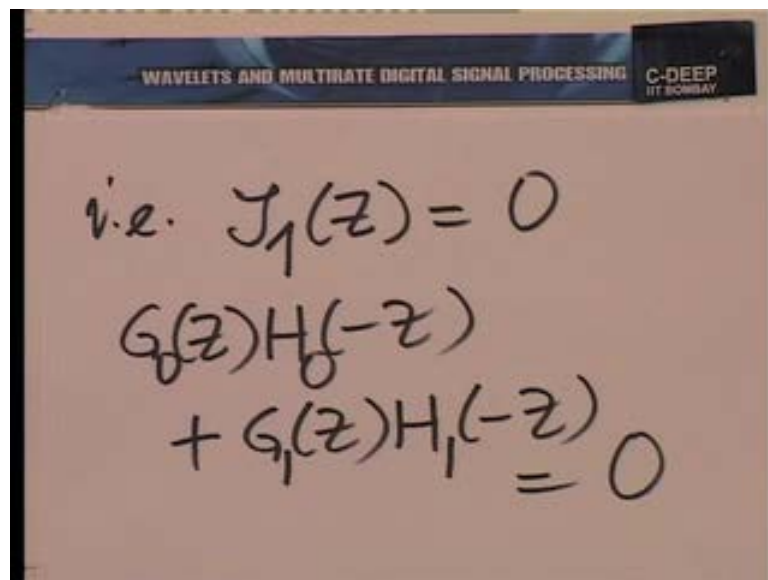

(Refer Slide Time: 41:30)

If we want  $Y Z$  to reconstruct  $X Z$ , we must first do away with aliasing and how can we possibly do away with aliasing. And how can we possibly do away with aliasing?

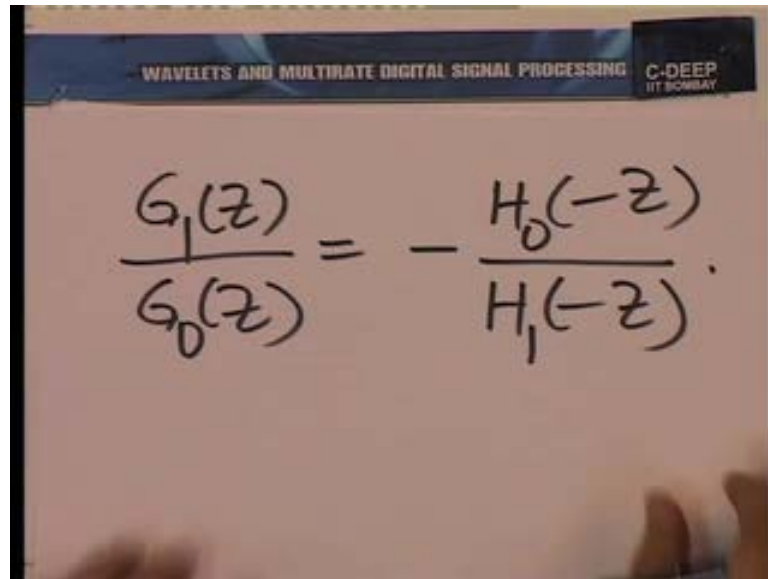

(Refer Slide Time: 42:06)

That essentially means, we want  $\tau_1 Z$  to be equal to 0 or in other words we want  $G_0 Z H_0 \text{ minus } Z$  plus  $G_1 Z H_1 \text{ minus } Z$  equal to 0. And in fact if we wish to explicitly express the synthesis filters in terms of the analysis filters we could do that as well.

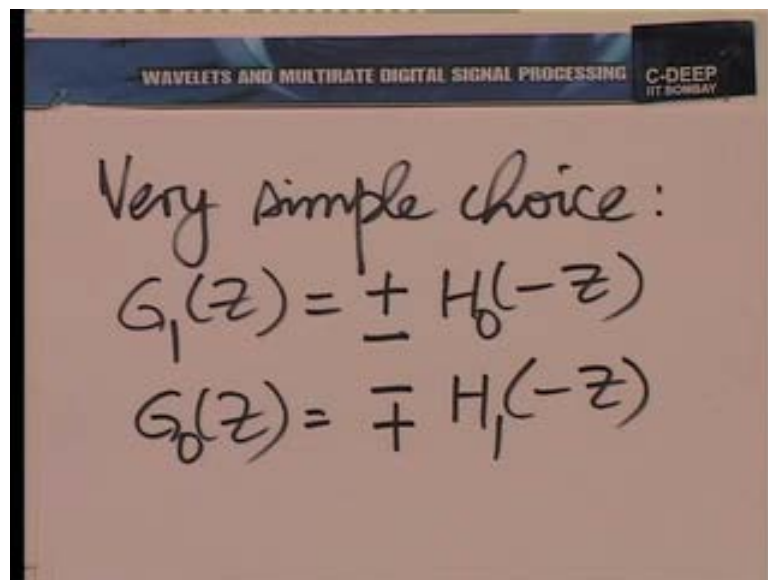

(Refer Slide Time: 42:46)

$$\frac{G_1(z)}{G_0(z)} = - \frac{H_0(-z)}{H_1(-z)}$$

Let us rearrange this equation to get  $G_1(z)$  by  $G_0(z)$  is minus  $H_0(-z)$  by  $H_1(-z)$ .

(Refer Slide Time: 43:07)

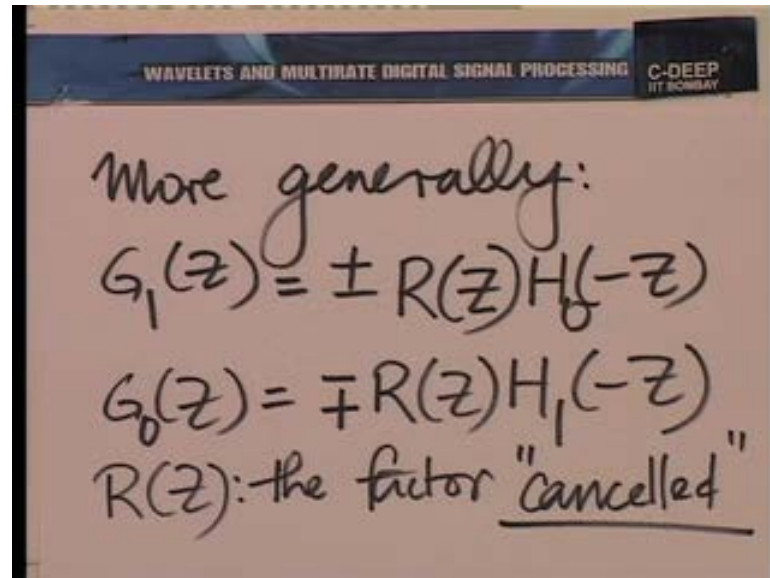

Very simple choice:

$$G_1(z) = \pm H_0(-z)$$
$$G_0(z) = \mp H_1(-z)$$

And of course, a very simple choice is  $G_1(z)$  equal to the numerator, let us say plus or minus  $H_0(-z)$  and correspondingly  $G_0(z)$  is minus respectively plus  $H_1(-z)$ . This is a very simple choice of synthesis filters from the analysis filters, which can give us alias cancellation. In fact, we can even spend a minute in interpreting what we have just said here in this very simple choice, I must of course emphasize, this is a simple

choice, but definitely not the only choice. In general, you should note that there would be a factor cancelled in the numerator and denominator. So, more general choice would be as follows.

(Refer Slide Time: 44:17)

$G_1(z)$  is of the form plus minus some factor let say  $R$  of  $z$  times  $H_0$  minus  $z$  and  $G_0(z)$  is respectively minus or plus  $R(z)H_1$  minus  $z$ . So,  $R(z)$  is in some sense the factor cancelled. When you divide  $G_0(z)$  by  $G_1(z)$ , some factor has been cancelled and what is left is  $H_0$  and  $H_1$  that is the way you should locate at it, that is the more general situation. Any way now let us interpret what we have written here? Namely  $G_1(z)$  this is the very simple choice of  $G_1$  is  $H_0$  of minus  $z$  and  $G_0$  is plus or minus, you just interchange plus or minus here  $H_1$  of minus  $z$ . Let us take the upper one  $G_1(z)$  is  $H_0$  minus  $z$ , the other one follows similarly.

(Refer Slide Time: 45:40)

You see ideally this is what the frequency response of  $H_0(z)$  should be, it should be an ideal low pass filter with a cutoff of  $\pi/2$ . So, this is what the frequency response should look like. This is 1 the height here. So, what would  $H_0(e^{j\omega})$  look like. In other words, what is  $H_0(-z)$  then?

(Refer Slide Time: 46:41)

$H_0(-z)$  with  $z$  replaced by  $e^{j\omega}$  is essentially of course as you know  $H_0(e^{j\omega})$  and that as you can very easily infer looks like this.

(Refer Slide Time: 46:59)

Again let us use the strategy of zooming and then contracting back again. I have  $\pi$  minus  $\pi$  there,  $2\pi$ ,  $3\pi$  and so on. This is what  $H_0$  look like taking note of the periodicity remember. This is  $\pi$  by  $2$  there, this is  $\pi$  by  $2$ , this would therefore be  $3\pi$  by  $2$  and so on.

So, the zoomed  $H_0 e^{j\omega}$  plus minus  $\pi$  would look like this.

(Refer Slide Time: 48:09)

It would have an appearance like this and so on here. This pass band so to speak and now going to lie at odd multiples of  $\pi$  and you can continue that drawing. Now once again, we confine to the principle interval, the principle interval is here.

And when we do so and then zoom back to emphasis only the principle interval what do we get?

(Refer Slide Time: 49:45)

We get this.

No in behold from a low pass filter with the cutoff of  $\pi$  by 2, we have a high pass ideal filter of course again with a cutoff of  $\pi$  by 2. So, this falls into place very well.

(Refer Slide Time: 50:59)

In fact, the equation  $G_1(z) = H_0(-z)$  makes a lot of sense.

All that we are saying is that on the synthesis side if you had an ideal low pass filter with a cutoff  $\pi/2$  at  $H_0$ , you should put an ideal high pass filter with cutoff  $\pi/2$  at the point  $G_1$ . And you know if you look back at the other one of the two namely  $G_0$ , you would make a similar inference,  $G_0(z) = H_1(-z)$  with the minus sign. So, if you look at that magnitude sense, again a high pass filter would become a low pass filter. In fact I leave this to you as an exercise.

(Refer Slide Time: 52:20)

Exercise show similarly, that an ideal high pass filter H P F with a cutoff  $\pi/2$  on replacing  $Z$  by  $1/Z$  becomes an ideal low pass filter with a cutoff of  $\pi/2$  and that also makes a lot of sense for the other of the two requirements for aliasing cancellation. So today, we have looked at the condition for alias cancellation and we interpreted the simplest of the conditions. Now, if you do not stick to the simple condition and if you have the factor of  $1/Z$  all that we need to do is to say that we are also modifying that filter a little beyond just this low pass to high pass and high pass to low pass conversion, that  $1/Z$  factor would carry out that modification.

So, we have taken one out of two steps today in building a perfect reconstruction two band filter bank, we have taken the step of aliasing cancellation. In the next lecture, we shall take the second step, namely perfect reconstruction. So, we have done away with  $1/Z$ , I mean  $1/Z$ , but now we need to see what to do with  $Z$ , which we shall do in the next lecture.
