Lecture No: # 17
The Uncertainty Principle

A warm welcome to 17th lecture on the subject of wavelets and multirate digital signal processing; we build in this lecture a very important principle. In fact, in some senses the principle that lies at the heart of the subject of wavelets and time frequency methods namely, the uncertainty principle. Therefore, as you note today, we shall devote the whole lecture to a discussion of the uncertainty principle; laying the foundation of what uncertainty means first and then proceeding to obtain certain numerical bounds on confinement in 2 domains simultaneously.

(Refer Slide Time: 00:56)

Let me first give an informal or a diffused non formal introduction to the idea of containment. Well, we did a little bit of that yesterday, in the previous lecture. But, what I intend to do now is to say a little more in terms of formality and then proceed to write down the mathematical relationships or definitions. Recall, we said that there is a very tight or a very strong kind of a notion of containment that would ask that you have compact support in both domains time and frequency. The function must be non-zero

strictly over a finite interval of the real axis and must be non-zero strictly over a finite interval of the real axis in the frequency domain as well.

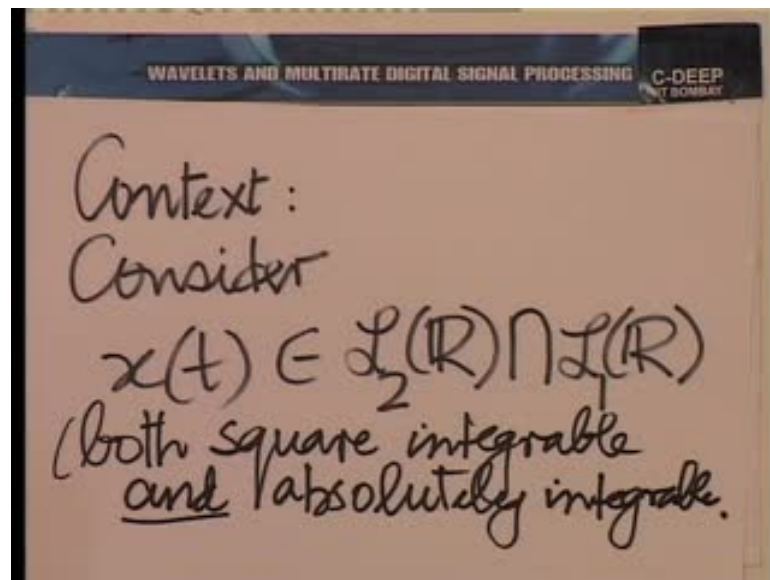

So, both in time and in frequency, you demand that the function be non-zero only over a finite part of the independent variable or the real axis. This is a very strong demand and yesterday we mentioned that it cannot be met ever. In fact, I also hinted at the idea behind the proof. It related to the fact that if you noted that the function was finitely supported, compactly supported on the real axis, there were certain properties of that function specifically the existence of an infinite number of derivatives which made it impossible for the function to be compactly supported or non-zero only on a finite interval of the independent variable in the natural domain. Natural domain can mean time, can mean space, whatever. Anyway, this was what we called the strong version of containment and we said that this was not possible. But, we had asked whether a weaker notion of containment could be admitted. Namely, we do not insist that the function be strictly non-zero over a finite interval but that most of its energy most of its content so to speak in some sense be on a finite interval of the independent variable which indexes it. Simultaneously, in the transform domain in the frequency domain we insist that most of the content be in a finite interval of the frequency axis this seems like a more reasonable requirement and to a certain extent this requirement can be met and as I said to give a diffused or a non-formal presentation of how it can be met, I shall begin this whole discussion by saying that we are finally going to come out with certain bounds on how much you can contain in the 2 domain simultaneously.

So there are several steps to reach this destination. The first step is to put down in a non-diffused, in a formal way what you mean by containment; what you mean by most of the content being in a certain finite range. We are also hinted at the approach we would take to do this briefly in the previous lecture.

We had said that there are 2 ways of looking at it. You could think of the magnitude squared of the function and the magnitude squared of the Fourier transform as a 1 dimensional object and then you could talk about the center of that object, center of mass if you like. You could talk about the spread of the object around the center of mass by using the notion of radius of gyration or if you prefer to speak in the language of probability densities, then you could employ the idea of the density built from the squared magnitude of the function and another density built from the squared magnitude

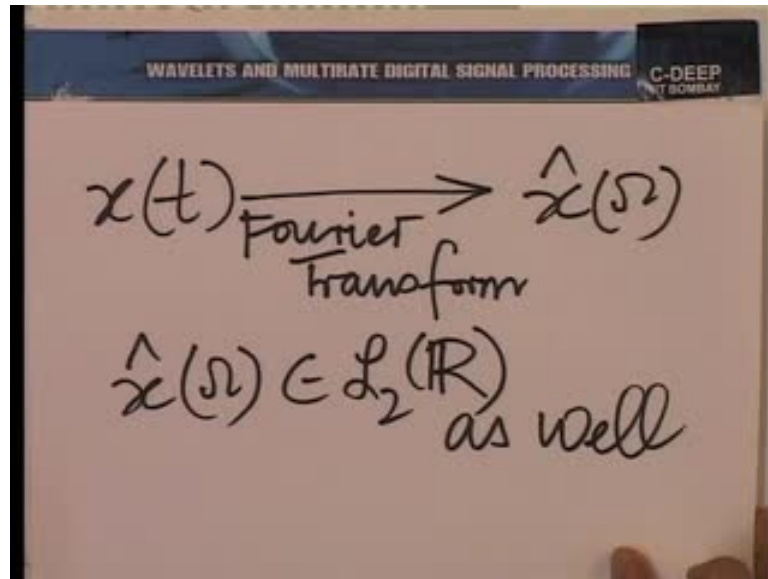

of the Fourier transform. You could then look at the mean of these densities and the variance of these densities. The variances are indicative of the spread; so this was a non-formal introduction. Now, we need to formalize it and that is what we shall do precisely. To begin with, put down formal definition, a formal explanation of the idea of spread.

(Refer Slide Time: 07:36)

Now, we have to define the domain in which we are going to work. We are going to work in L_2 we had agreed to that. It is always going to be the space of square integral functions. In fact, I must mention that sometimes we are actually going to work in the intersection of the space of square integrable functions and absolutely integrable functions. To be on the safe side, let us put down that requirement right now and let us put down the test of the requirements; namely, that the function belongs to the intersection of these 2. So, the context: consider, a function let say x of t which belongs to the intersection of $L_2 \mathbb{R}$ and $L_1 \mathbb{R}$ which means it is both square integrable and absolutely integrable; I think we should note that.

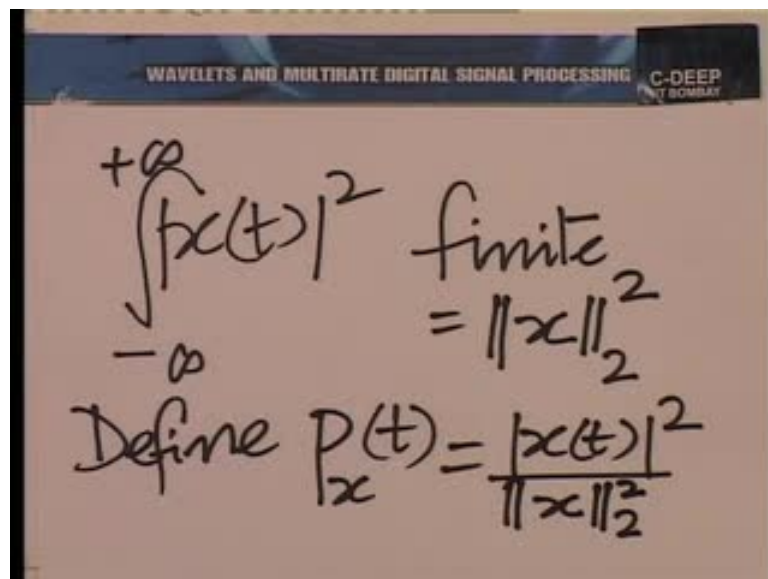

(Refer Slide Time: 08:54)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP T BOMBAY

$$x(t) \xrightarrow{\text{Fourier Transform}} \hat{x}(\omega)$$
$$\hat{x}(\omega) \in L_2(\mathbb{R}) \text{ as well}$$

(Refer Slide Time: 10:15)

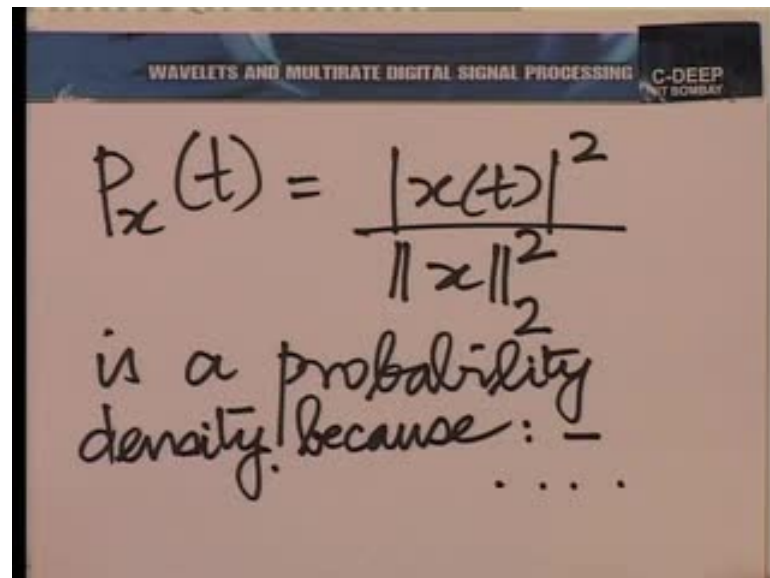

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP T BOMBAY

$$\int_{-\infty}^{+\infty} |x(t)|^2 dt \text{ finite} = \|x\|_2^2$$
$$\text{Define } P_x(t) = \frac{|x(t)|^2}{\|x\|_2^2}$$

Alright, now because the function belongs to $L_2 \mathbb{R}$, we are sure that its Fourier transform also belongs to $L_2 \mathbb{R}$. so let us $x(t)$ have the Fourier transform $\hat{x}(\omega)$ and we know that $\hat{x}(\omega)$ belongs to $L_2 \mathbb{R}$ as well. So, we first define a density or a 1 dimensional mass if you would like to call it that. We know that both $x(t)$ and $\hat{x}(\omega)$ are square integrable and therefore, if we take the magnitude squared of $x(t)$ and the magnitude squared of $\hat{x}(\omega)$, they would enclose a finite area under. In fact, the 2 areas would be essentially the same but for the factor of 2π . Again, if we chose to do away with angular frequency and used hertz

frequency, that 2π factor would also go away. Anyway, what we are saying is, $|x(t)|^2$ squared integrated from minus to plus infinity is finite let us in fact use the standard notation for this the norm of x in $L^2 \mathbb{R}$ the whole squared and therefore define a density P_x (Refer Slide Time: 11:10) given by $|x(t)|^2$ divided by the norm again squared.

(Refer Slide Time: 11:23)

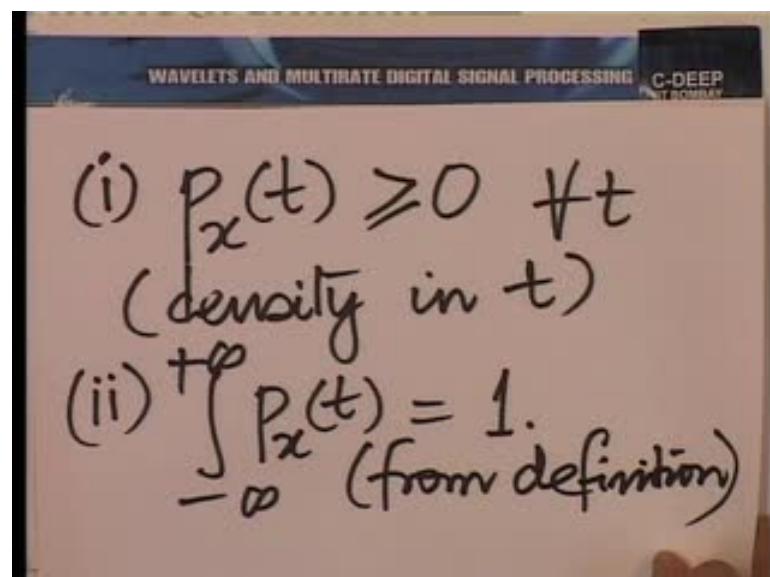

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP
MUMBAI

$$P_x(t) = \frac{|x(t)|^2}{\|x\|_2^2}$$

is a probability density because: -
.....

(Refer Slide Time: 11:59)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP
MUMBAI

(i) $P_x(t) \geq 0 \quad \forall t$
(density in t)

(ii) $\int_{-\infty}^{+\infty} P_x(t) dt = 1.$
(from definition)

Now, a few remarks and in fact, we should write them down one by one. $P_x(t)$ as we defined it namely, $|x(t)|^2$ divided by the norm in $L^2 \mathbb{R}$ of x the whole squared is a

probability density. Why do we say this? Well, because of the following reasons: let us list them one by one. Number 1: $P \times t$ is greater than equal to 0 for all t it is a density in t . Of course, see you may think of t as a random variable and this is the density on that the integral over all t of $P \times t$ is easily seen to be 1 from the definition. Essentially, the integral of $P \times t$ over all t would in the numerator again have the L 2 norm of the function x and of course, the denominator is indeed the L 2 norm of the function x both squared the numerator and denominator and therefore, they would cancel out to give 1.

(Refer Slide Time: 13:11)

The image shows a handwritten equation on a slide. The text reads: "Similarly define $P_{\hat{x}}(\omega) = \frac{|\hat{x}(\omega)|^2}{\|\hat{x}\|_2^2}$ ". The slide has a header that says "WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING" and "G-DEEP T. SOMBAY".

Similarly, let us define a density in the Fourier domain in the angular frequency domain. There we shall write $P \times \text{cap}$ as a function of ω to be $\text{mod } x \text{ cap } \omega$ squared divided by the norm of $x \text{ cap}$ squared. Here again, we are assured of the denominator being finite because of the L 2 R business.

(Refer Slide Time: 14:08)

(Refer Slide Time: 15:27)

So, again we shall for completeness and formalism, note that this is the probability density. $P_{\hat{x}}(\omega)$ is also a probability density. Indeed, $P_{\hat{x}}(\omega)$ is greater than equal to 0 for all ω ; it is the density in ω . The integral over all ω from minus to plus infinity of $P_{\hat{x}}$ is 1. That is also easy to see by very definition.

(Refer Slide Time: 16:47)

Now, we have taken the probability density perspective but, we could as well take the so called 1 dimensional mass perspective and let me also note that. One could also take a 1 dimensional mass perspective. That is, we could think of $P \times t$ as a 1-D mass in t and similarly, you could think of $P \times \text{cap } \omega$ as a 1 dimensional mass in ω . So, what I am saying is, all of us or all the objects around us are masses in 3 dimensional space so here we have a simplified situation you have a mass in 1 dimensional space; that 1 dimensional space can be the space of t or the space of capital ω . Similarly, as I said $p \times \text{cap } \omega$ is a one dimensional mass.

(Refer Slide Time: 17:37)

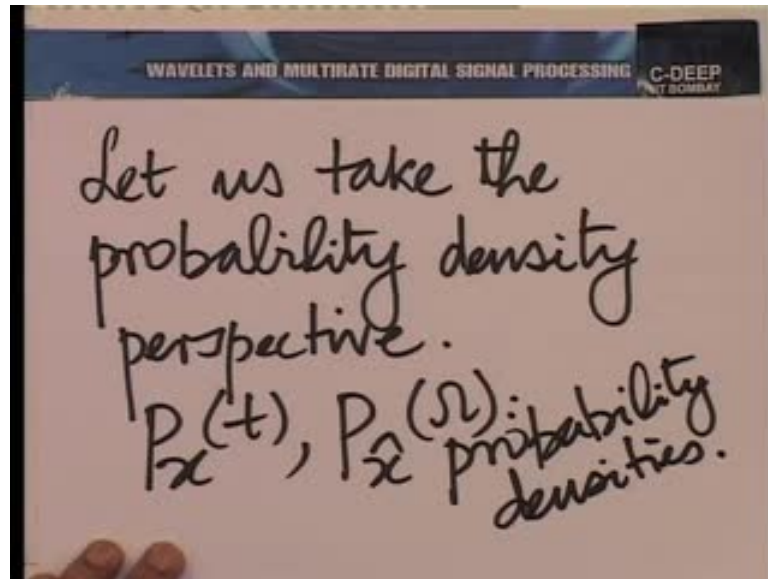

(Refer Slide Time: 18:36)

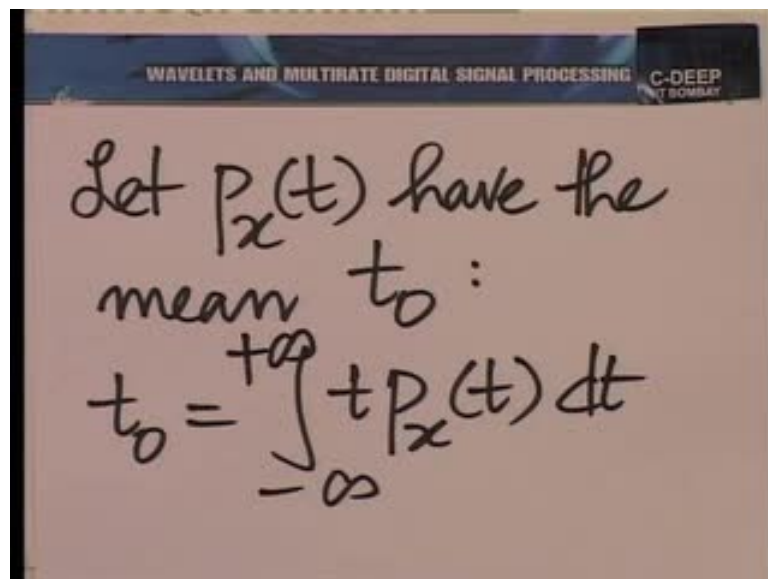

Now, once you take the mass perspective then immediately, you have the notion of centre of mass, centre of gravity if you like to call it that and when you take a probability density perspective you have the notion of mean. Either of them is they are equivalent; so let us make a note of that. If we choose the mass perspective, consider the centre of mass and spread around the center. Now, incidentally as I said the spread around the centre in mechanics is often measured by quantity called the radius of gyration. If we happen to take the density perspective, consider the mean and the variance. Now, we must assume that these quantities can be calculated and we shall do that. It is possible that the variance be infinity; that is a subtle point. So, we are not always guaranteed of finite variance and in fact, that is not a contradiction to what we have been saying so far. We are trying to find a lower limit to where the quantities go in the 2 domains simultaneously. So, if the variance happens to be infinite which it will actually in some situations, we shall simply say that is the worst possible case that we can encounter.

(Refer Slide Time: 20:24)

(Refer Slide Time: 21:11)

Anyway, let us consider given this function $x(t)$ we will prefer to take the probability density perspective. So, we will think of $P_x(t)$ and $P_{\hat{x}}(\omega)$ as probability densities and we will then write down the mean. So, indeed let $P_x(t)$ have the mean t_0 , what would that mean? t_0 would then be $\int_{-\infty}^{+\infty} t P_x(t) dt$ over all t from minus to plus infinity. Simple, the definition of mean; you recognize the same definition, to hold good for the centre of mass here. Essentially, you are calculating the moment by choosing the fulcrum to be 0 and therefore, getting a different fulcrum or a point at which the moments are all balanced.

(Refer Slide Time: 22:10)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP
T BOMBAY

Similarly let $p_{\hat{x}}(\omega)$
have the mean ω_0

$$\omega_0 = \int_{-\infty}^{+\infty} \omega p_{\hat{x}}(\omega) d\omega$$

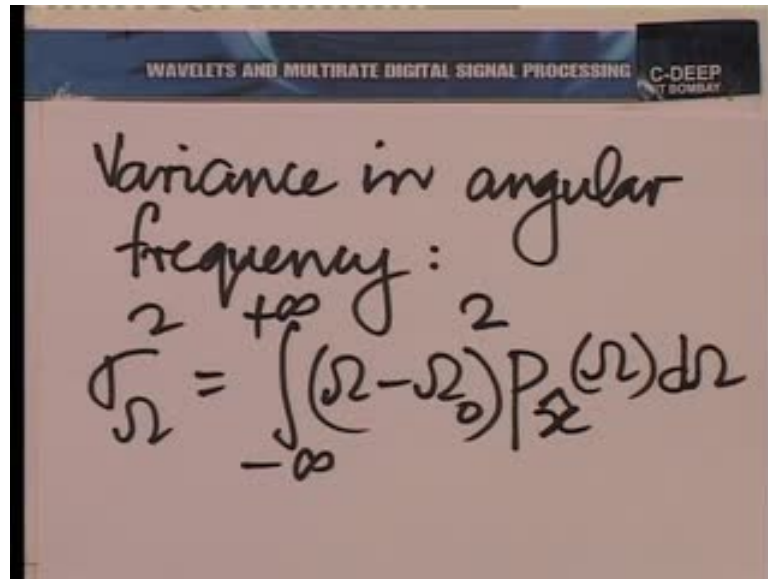

(Refer Slide Time: 23:12)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP
T BOMBAY

Variances:
variance in t :

$$\sigma_t^2 = \int_{-\infty}^{+\infty} (t-t_0)^2 p_x(t) dt$$

(Refer Slide Time: 24:03)

The image shows a handwritten slide with the following text and equation:

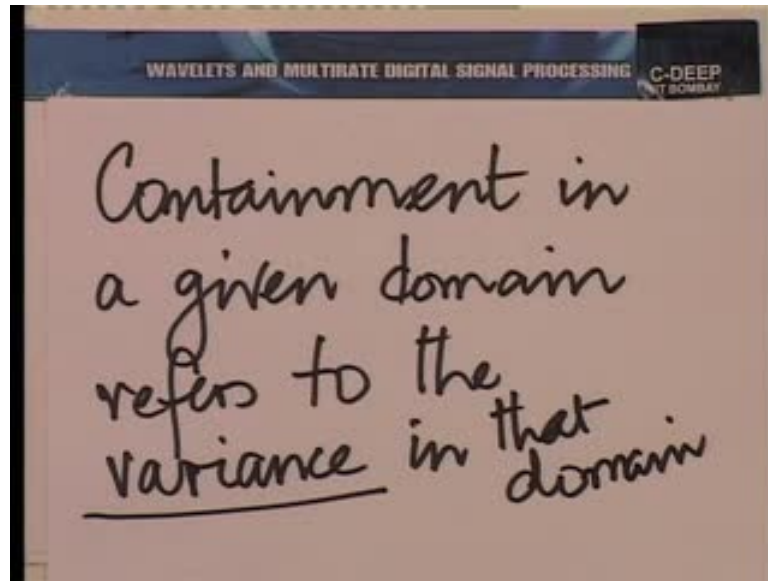

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP TROMBAY

Variance in angular frequency:

$$\sigma_{\Omega}^2 = \int_{-\infty}^{+\infty} (\Omega - \Omega_0)^2 P_{\Omega}(\Omega) d\Omega$$

Similarly, let P_x have the mean ω_0 , whereupon ω_0 would be integral from minus to plus infinity $\omega P_x(\omega) d\omega$; again, the centre of mass, if you like to look it at that way, in the frequency domain. Now, once we have the mean and just as a tongue-in-cheek statement, we assume the means are finite. Normally, they should be in some pathological situations we may have a problem we are not looking at those pathological situations. So, assuming these means are finite, let us look at the variance, so the variance in t would then be given by and we will define it to be σ_t^2 by definition; this should be $(t - t_0)^2$ times $P_x(t)$ integrated over all t . Similarly we could talk about the variance in frequency. So, variance in angular frequency; σ_{Ω}^2 is integral from minus to plus infinity, $(\Omega - \Omega_0)^2 P_{\Omega}(\Omega) d\Omega$. Once again, tongue-in-cheek, we are assuming these variances to be finite. In any case, here we do not have such a problem even if the variances are infinite we will accept it. We will say that it is the extreme. In the worst case, whatever they be, finite or infinite, we accept.

(Refer Slide Time: 26:16)

Now, it is very clear; you see, if you look at a probability density or perhaps, if you **to** choose to think of this as one dimensional masses, it is very clear that the variance is an indication of the spread. So, the larger the variance the more the density is set to have spread around the mean. The smaller the variance, the more the density on the mass is said to be concentrated. Now, we have a formal way to define containment. In fact, we shall now make a very simple definition. We will say containment in that particular domain refers to the variance or if you like the square root of the variance, positive square root. So, let us put down this statement formally. We will say containment in a given domain refers to the variance in that domain. So, containment in time is essentially the σ_t^2 quantity and containment in the angular frequency is essentially the σ_ω^2 quantity. Now, we ask ourselves how small can we make any one of these quantities for a function, for a valid function. In a few minutes we will be convinced there is really there is no limit. In fact, let us take the haar scaling function as an example; let us calculate the variance.

(Refer Slide Time: 27:26)

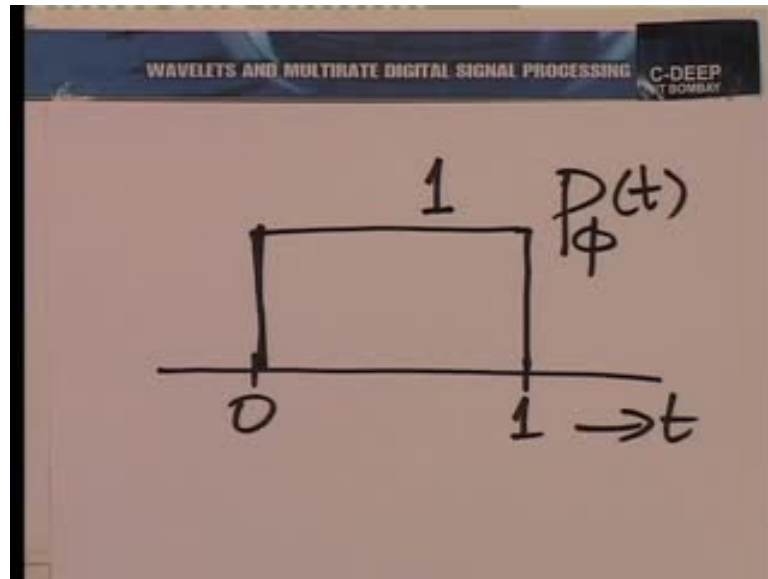

(Refer Slide Time: 28:10)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP BOMBAY

$$P_{\phi}(t) = \frac{|\phi(t)|^2}{\|\phi\|_2^2}$$
$$\|\phi\|_2^2 = 1 = \int_{-\infty}^{+\infty} |\phi(t)|^2 dt$$

(Refer Slide Time: 28:50)

(Refer Slide Time: 29:30)

The figure shows a hand-drawn mathematical derivation for the mean t_0 of the Haar scaling function. The derivation is as follows:

$$t_0 = \int_{-\infty}^{+\infty} t P_\phi(t) dt$$
$$= \int_0^1 t \cdot dt = \left. \frac{t^2}{2} \right|_0^1 = \frac{1}{2}$$

You see the haar scaling function ϕ of t is 1 between 0 and 1 and 0 else and then of course, it is very easy to write down the density here. It is very easy to see that the squared norm in $L^2 P$ of ϕ is 1. It is essentially the integral $\phi^2 dt$ over all t ; easily seem to be 1 and therefore, very luckily P_ϕ looks very much like ϕ . This is how P_ϕ looks. Our job is easy; let us find the mean. In fact, even before I formally set out to find the mean I can estimate the mean graphically. The mean is going to be in the centre at half; that is obvious. But, let us do it formally. So, t_0 would be $\int t P_\phi(t) dt$ over all t and this essentially mounts to $\int t dt$ from 0 to 1 so I

have replaced $P_\phi(t)$ by 1 and I have replaced the limits by 0 to 1. This is obviously t squared by 2 evaluated from 0 to 1 which indeed is nothing but half, as we expected; so the mean is indeed half.

(Refer Slide Time: 30:17)

(Refer Slide Time: 30:50)

Hand-drawn equation for the variance of the pulse function. The equation is: Variance: $\int_{-\infty}^{+\infty} (t - \frac{1}{2})^2 P_\phi(t) dt$. The slide header reads "WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING" and "C-DEEP IIT BOMBAY".

(Refer Slide Time: 31:27)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP IIT BOMBAY

$$= \int_0^{1/2} \left(t - \frac{1}{2}\right)^2 dt$$

$t - \frac{1}{2} = \lambda$

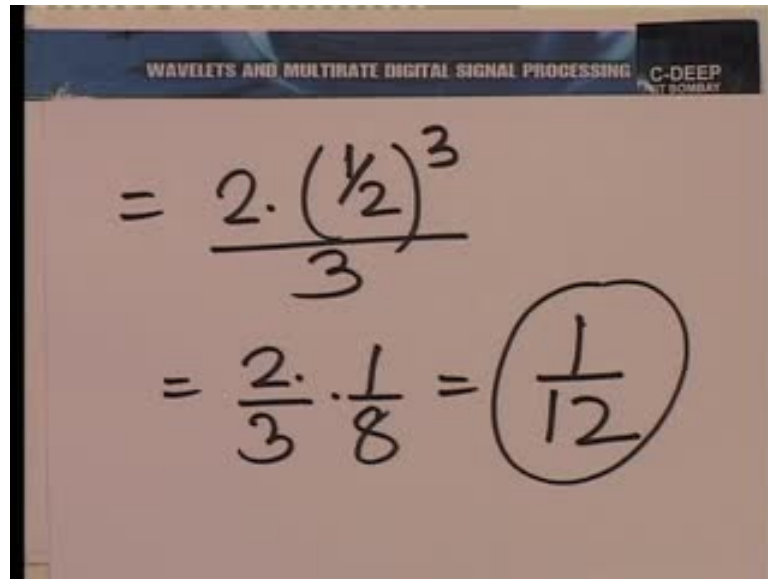

$$= \int_{-1/2}^{1/2} \lambda^2 d\lambda$$

(Refer Slide Time: 32:10)

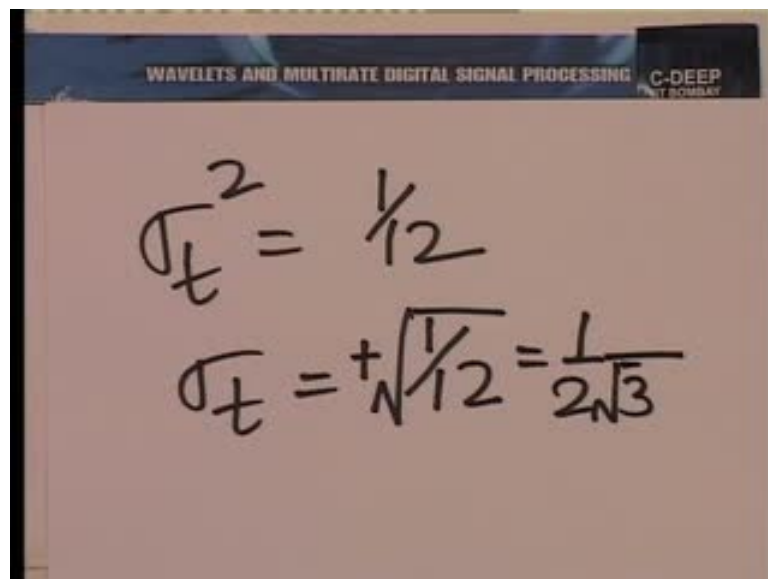

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP IIT BOMBAY

$$= \frac{\lambda^3}{3} \Big|_{-1/2}^{1/2}$$
$$= \frac{\left(\frac{1}{2}\right)^3}{3} - \left(-\frac{\left(\frac{1}{2}\right)^3}{3}\right)$$

(Refer Slide Time: 32:40)

$$= \frac{2 \cdot \left(\frac{1}{2}\right)^3}{3}$$
$$= \frac{2}{3} \cdot \frac{1}{8} = \left(\frac{1}{12}\right)$$

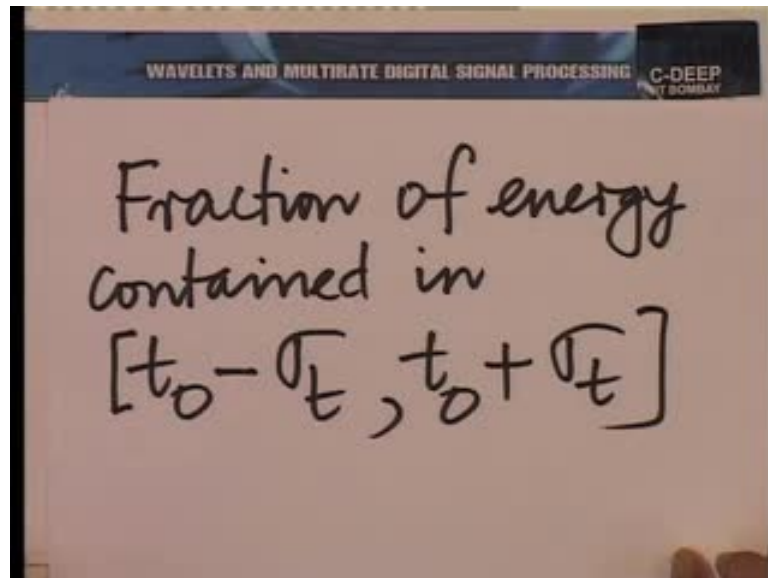

(Refer Slide Time: 33:05)

$$\sigma_t^2 = \frac{1}{12}$$
$$\sigma_t = \sqrt{\frac{1}{12}} = \frac{1}{2\sqrt{3}}$$

Now, we need to calculate the variance that is little more work but, not too much variance. Indeed, the variance would be given as $\int_0^1 t^2 \phi(t) dt$ over all t . Once again, noting that $\phi(t)$ is 1 only between 0 and 1 and 0 else, we can rewrite this to get $\int_0^1 t^2 dt$ and if I care just to replace t by another variable λ , I would get this to be well when t is 0 λ would take the value 0; when t is 1 λ would take the value 1. This would be $\int_0^1 \lambda^2 d\lambda$ to be integrated and then we have an easy expression. So, let us $\frac{1}{3} - \frac{0}{3}$ and therefore, you have 2

times half cubed by 3 which is 2 by 3 into 1 by 8 or 1 by 12. So, this is the variance now σ_t^2 is 1 by 12 and therefore, you may take σ_t to be square root the positive square root of 1 by 12 which is 1 by 2 square root 3; as you can see it σ_t is less than half.

(Refer Slide Time: 34:15)

(Refer Slide Time: 34:51)

So, in a certain sense we do not really use the number half to denote the spread of $\phi(t)$ around its mean. The variance does not say it whole all the way to half; it says the spread is a number slightly less than half. Most of the energy is contained in that region around

the mean captured by the variance. In fact, if you wish to be very specific the fraction of the energy contained here would be, **it is essentially**, would be the integral of the density between $t_0 - \sigma t$ to $t_0 + \sigma t$. So, that would essentially be now... I do not really intend to calculate this quantity for this case; it is a very simple calculation of course integrated with respect to t but, what I am trying to emphasize is, we are asking for 100 percent.

(Refer Slide Time: 35:43)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP T BOMBAY

$$= \int_{\frac{1}{2} - \frac{1}{2\sqrt{3}}}^{\frac{1}{2} + \frac{1}{2\sqrt{3}}} 1 dt = \dots$$

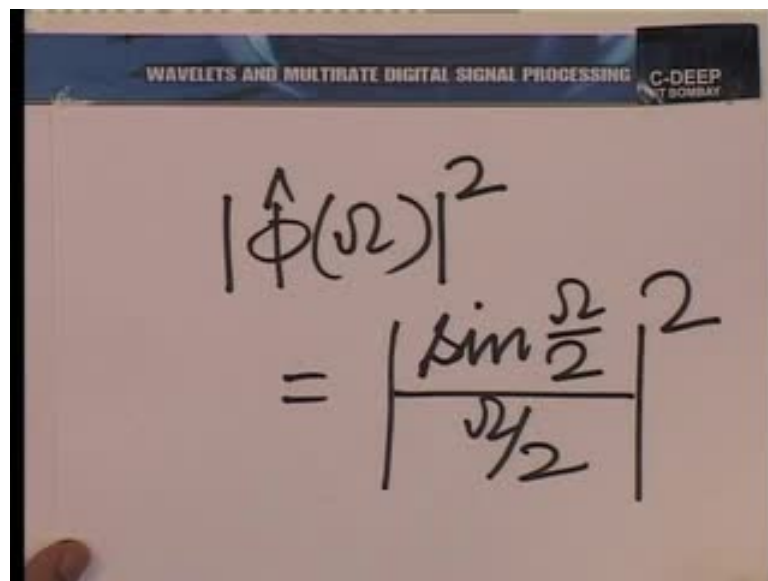

(Refer Slide Time: 36:04)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP T BOMBAY

$$= t \Big|_{\frac{1}{2} - \frac{1}{2\sqrt{3}}}^{\frac{1}{2} + \frac{1}{2\sqrt{3}}} = 2 \cdot \frac{1}{2\sqrt{3}} = \frac{1}{\sqrt{3}}$$

We are saying, tell me the region over which 100 percent of the energy lies that region could very well be the whole real axis. We are saying well, at least a significant part of it. Now, in this particular case may be it is a good idea to actually calculate it, how much is this really. So, it is actually and this is essentially so; it is t evaluated from half minus, so this is easily seen to be, 2 times 1 by 2 under root 3 which is 1 by square root of 3. Now, certainly not a very large fraction like 90 percent; what is about 1 by 1 point 7 more than 50 percent anyway. Incidentally, this fraction is not going to be the same for the different function. It depends on the density but, what we are trying to say is that the variance is one accepted measure of spread and very often the variance actually tells us where most of the function is concentrated. Even in the case of this function, if you look at it carefully, what we are saying is quite a bit of the function is contained between half minus 1 by 2 square root 3 and half plus 1 by 2 square root 3. So, it is not an unreasonable range that we choose.

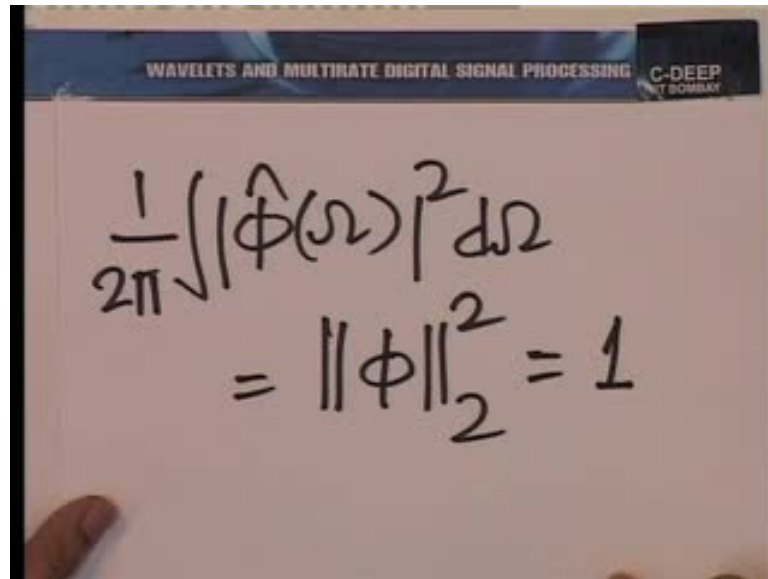

(Refer Slide Time: 38:03)

The image shows a whiteboard with handwritten mathematical equations. At the top, there is a blue header with the text "WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING" and "C-DEEP BOMBAY". The main equation is written in black ink and shows the squared magnitude of the Fourier transform of a sinc function. The equation is:

$$|\hat{\phi}(\omega)|^2 = \left| \frac{\sin \frac{\omega}{2}}{\omega/2} \right|^2$$

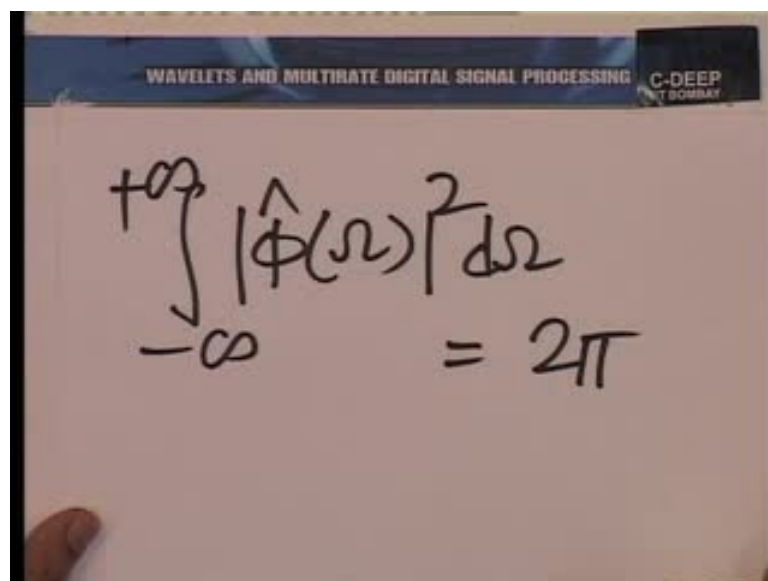

(Refer Slide Time: 38:38)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP T BOMBAY

$$\frac{1}{2\pi} \int |\hat{\phi}(\Omega)|^2 d\Omega = \|\phi\|_2^2 = 1$$

(Refer Slide Time: 39:01)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP T BOMBAY

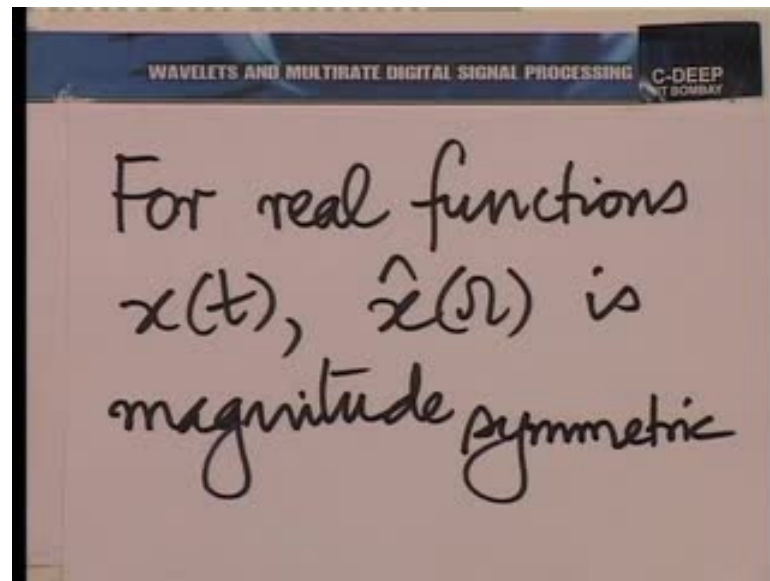

$$\int_{-\infty}^{+\infty} |\hat{\phi}(\Omega)|^2 d\Omega = 2\pi$$

(Refer Slide Time: 39:22)

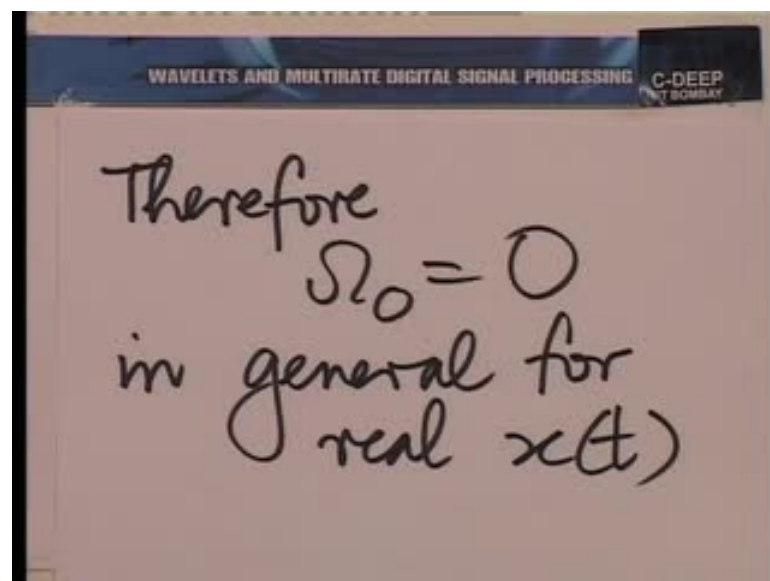

Now, we ask about the variance in frequency of the same function and there we are going to have a very pleasant or unpleasant surprise. So, let us look at $\hat{\phi}(\omega)$. In fact, we are so interested in $\hat{\phi}(\omega)$; we are interested in $|\hat{\phi}(\omega)|^2$ and that has the form. Essentially, $\frac{\sin(\omega/2)}{\omega/2}$ the whole squared mod and you could integrate this you know, indeed as you know the integral of $|\hat{\phi}(\omega)|^2 d\omega$ divided by 2π would essentially, be the norm of ϕ in L^2 norm of ϕ the whole squared, which is easily seen to be 1. Therefore, $\int_{-\infty}^{\infty} |\hat{\phi}(\omega)|^2 d\omega$ over all ω is essentially 2π . Therefore, we essentially look at the quantity $|\hat{\phi}(\omega)|^2$ rather which is essentially of the form $|\hat{\phi}(\omega)|^2$ divided by 2π . Let me sketch this; in fact, we are familiar with it, would have an appearance like this is 0, this is 2π , 4π and so on. So far, we know this; we have been doing this more than once.

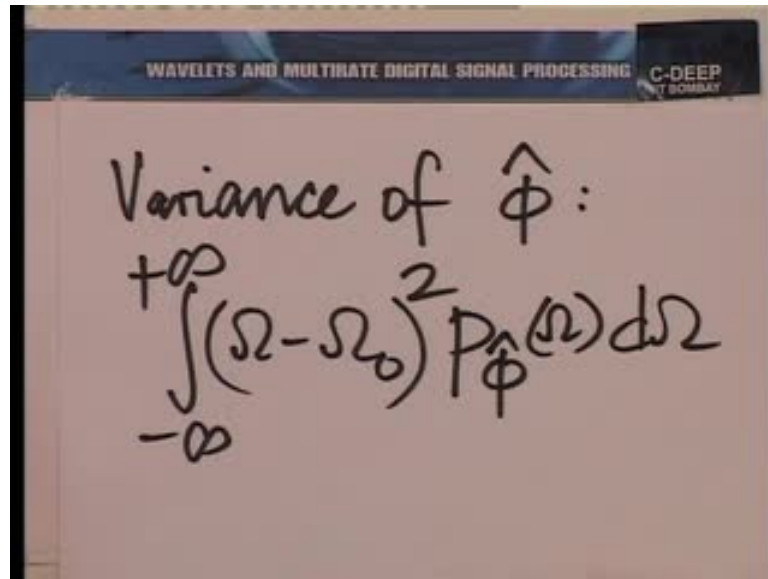

(Refer Slide Time: 41:07)

(Refer Slide Time: 41:35)

(Refer Slide Time: 42:12)

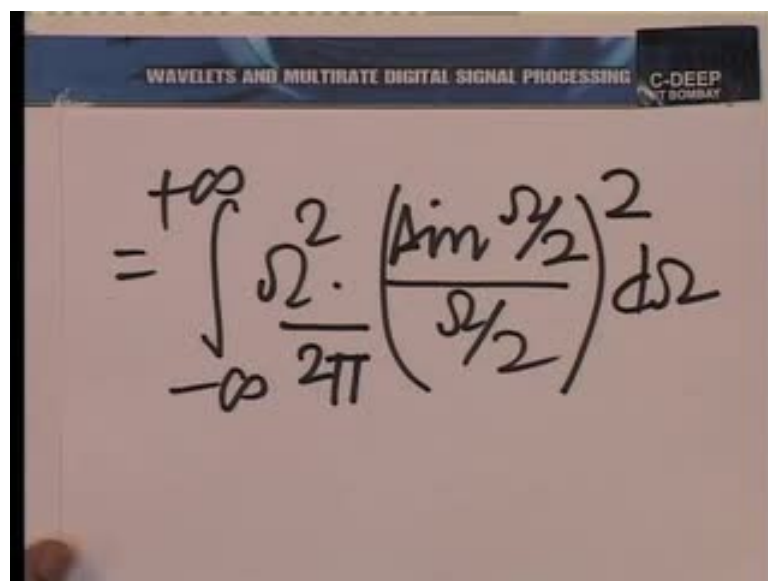

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP T BOMBAY

Variance of $\hat{\phi}$:

$$\int_{-\infty}^{+\infty} (\Omega - \Omega_0)^2 P_{\hat{\phi}}(\Omega) d\Omega$$

(Refer Slide Time: 42:42)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP T BOMBAY

$$= \int_{-\infty}^{+\infty} \Omega^2 \cdot \frac{2}{2\pi} \left(\frac{\text{Im} \Omega/2}{\Omega/2} \right)^2 d\Omega$$

(Refer Slide Time: 43:09)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP T BOMBAY

$$= \int_{-\infty}^{+\infty} \frac{4}{2\pi} \sin^2 \frac{\omega}{2} d\omega$$

not important

trouble!

(Refer Slide Time: 43:47)

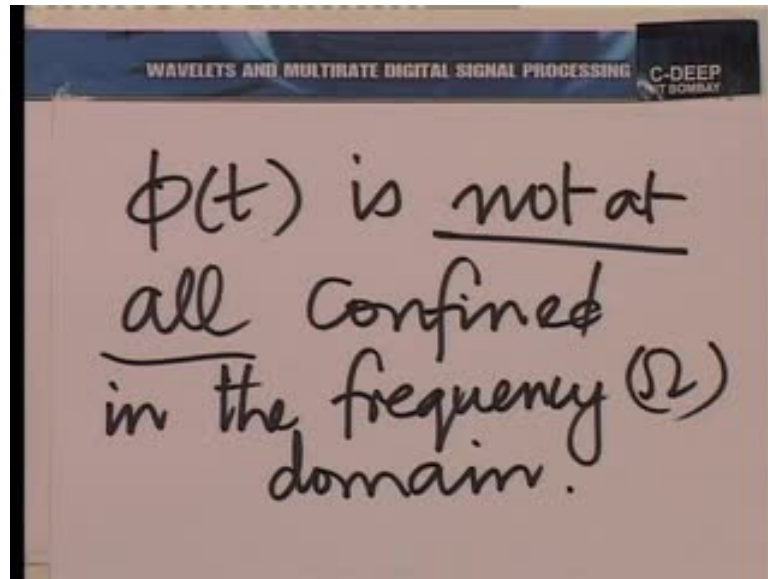

Now, it is very easy to see what the mean of this function is. The function is symmetric around $\omega = 0$ and therefore, the mean is 0. By the way, this is not a surprise for many real functions. We would find the mean for all real functions; the mean of the density on the frequency axis is going to be 0. The Fourier transform for real function is magnitude symmetric and therefore, it is not surprising that for a real function the mean as understood in this sense, is always going to be 0 on the frequency axis. Let us make a note of that; it is a very important conclusion. For real functions, $X(\omega)$ is magnitude symmetric; therefore, the mean is 0. Now, comes the variance and here we

have a very unpleasant surprise waiting for us. I say unpleasant because, maybe we should have something better. So, the variance of $\hat{\phi}$ would be calculated as follows: integral over all ω minus ω naught the whole squared $P \hat{\phi}(\omega)$ $d\omega$ and if we make the required substitutions we have this is essentially ω squared times $\sin(\omega/2)$ divided by $\omega/2$ the whole squared divided by 2π here $d\omega$ and here we are in serious trouble this is integral minus to plus infinity $1/2\pi \sin^2(\omega/2)$ times 4 so 4 goes up there $d\omega$. This is not important, just a constant; but, this is trouble, we are in serious trouble here. In fact, let me sketch what we are trying to integrate. This function, a periodic function with a period of $2\pi \sin^2(\omega/2)$ serious trouble as I said.

(Refer Slide Time: 44:45)

(Refer Slide Time: 45:06)

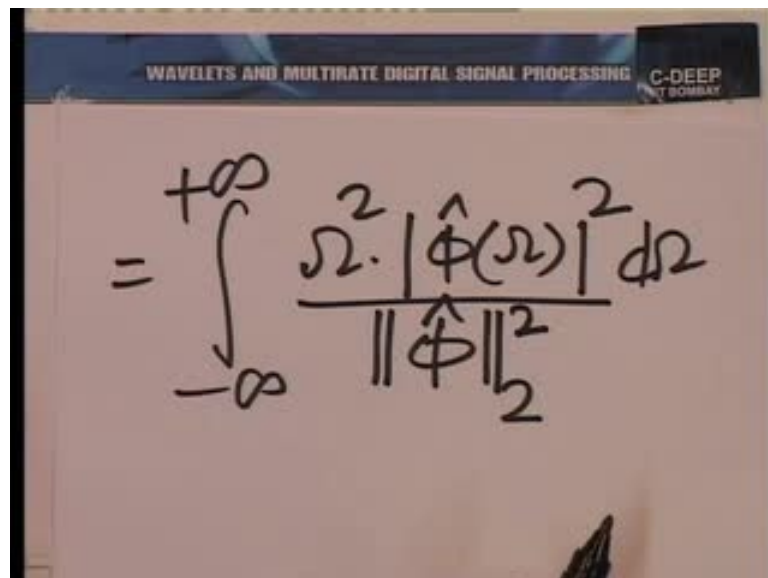

(Refer Slide Time: 47:35)

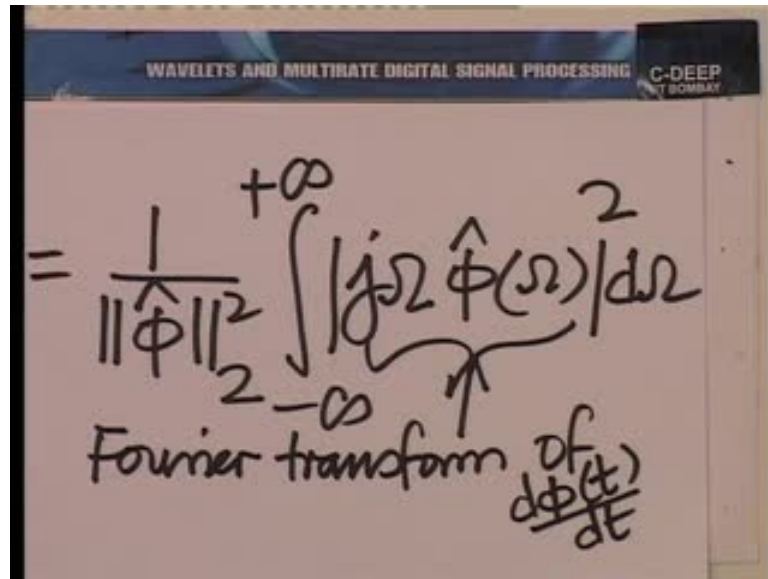

We are trying to integrate a periodic function from minus to plus infinity and obviously, that integrate is going to diverge. So, the fear that we had when we started with discussion with variance comes out to be true, right in the very simplest case of a scaling function that we know. The variance of ϕ cap is infinite; in other words, ϕ t is not at all confined in the frequency domain, at least in this sense. Now, all this... why in our discussion when we talked about time and frequency together and so on? The previous lecture we had been worried about the side lobes, as we call them. We said well, it is alright to look at the main lobe and talk about presence in the main lobe. But, then we

have the side lobes and the side lobes are falling off only by the factor $1/\omega$ in magnitude. As you can see, the side lobes have created a problem after multiplication by ω^2 in the calculation of variance. The side lobes create a periodic function to be integrated; a periodic non negative function and we are in trouble. So, this tells us again why we have to go much beyond the Haar. We have been asking again and again, why we cannot be content with the Haar multi resolution analysis. Now, we have one more formal answer. If we look at the scaling function for the Haar multi resolution analysis, it is variance. In the frequency domain it is not at all confined in the frequency domain in the sense.

(Refer Slide Time: 48:03)

$$= \int_{-\infty}^{+\infty} \frac{\omega^2 |\hat{\phi}(\omega)|^2}{\|\hat{\phi}\|_2^2} d\omega$$

(Refer Slide Time: 48:37)

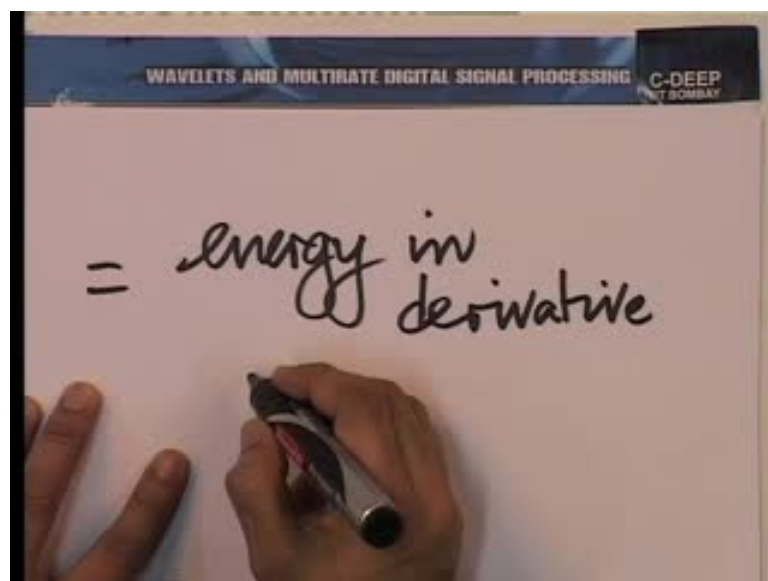

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP T BOMBAY

$$= \frac{1}{\|\hat{\phi}\|_2^2} \int_{-\infty}^{+\infty} |j\omega \hat{\phi}(\omega)|^2 d\omega$$

Fourier transform of $\frac{d\phi(t)}{dt}$

(Refer Slide Time: 49:53)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP T BOMBAY

= energy in derivative

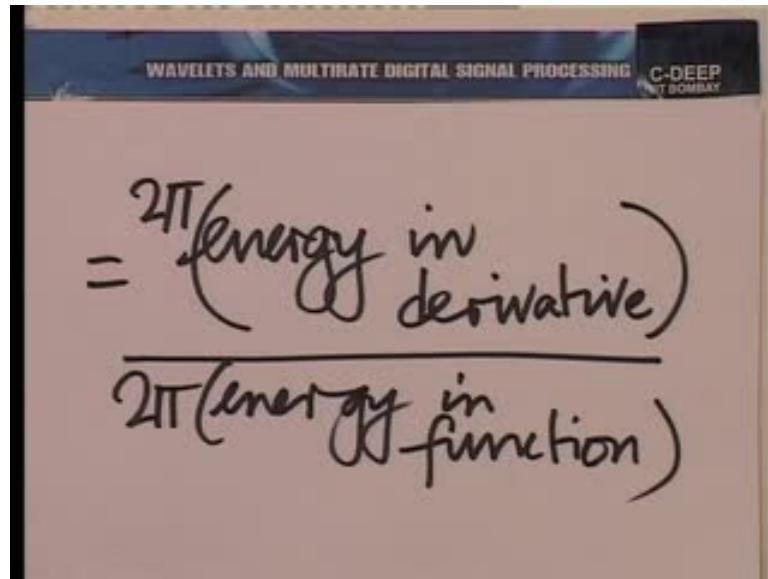

(Refer Slide Time: 50:11)

$$= \frac{1}{\|\hat{\phi}\|_2^2} \int_{-\infty}^{+\infty} |j\omega \hat{\phi}(\omega)|^2 d\omega$$

Fourier transform of $\frac{d\phi(t)}{dt}$

Now, it is a natural question to ask what is it that made this variance infinite? Why did we have a divergent variance here? In fact, we can answer that question if you only care to make a slight adjustment of the expression of variance. The variance of $\hat{\phi}$ is finally, as you can see, given by $\int \omega^2 |\hat{\phi}(\omega)|^2 d\omega$ and this can be written as $\int \omega^2 |\hat{\phi}(\omega)|^2 d\omega$ divided by the norm of $\hat{\phi}$ in $L^2(\mathbb{R})$ the whole squared. Now, this norm is a number; it can be brought out of the integral. So, I can rewrite this as $\frac{1}{\|\hat{\phi}\|_2^2} \int \omega^2 |\hat{\phi}(\omega)|^2 d\omega$ and I also do a little bit of rearrangement in the integral. I will write the integral as $\int |j\omega \hat{\phi}(\omega)|^2 d\omega$. Notice, that if I take the modulus of $j\omega \hat{\phi}(\omega)$, it is essentially modulus ω^2 times modulus $|\hat{\phi}(\omega)|^2$. Modulus ω^2 and ω^2 are the same for the ω real, but then when we write it like this has a meaning. It is essentially the Fourier transform of $\frac{d\phi(t)}{dt}$, Fourier transform of the derivative of ϕ . So, essentially what we are saying is this variance is actually the energy in the derivative.

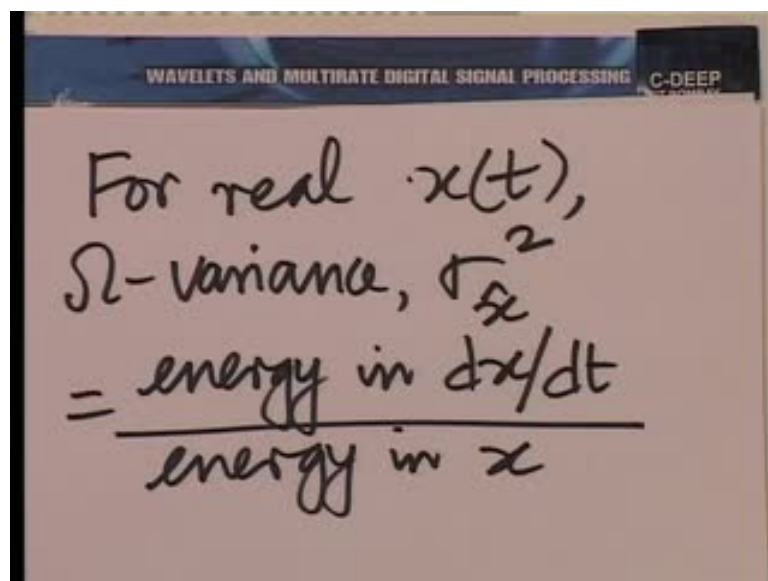

(Refer Slide Time: 50:24)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP BOMBAY

$$= \frac{2\pi (\text{energy in derivative})}{2\pi (\text{energy in function})}$$

(Refer Slide Time: 50:57)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP BOMBAY

For real $x(t)$,
 Ω -variance, σ_{Ω}^2
 $= \frac{\text{energy in } dx/dt}{\text{energy in } x}$

Remember, you would have a factor of 2π there because, this is the energy in the derivative. But, for a factor of 2π ... So, this would be 2π times the energy in the derivative divided by 2π times the energy in the function. Please note that this inference that we have made is independent of what function we consider as long as the function is real. The variance in frequency is going to be this ratio: the energy in the derivative divided by the energy in the function. Let us make that remark for real functions, for real $x(t)$; the frequency variance Ω variance or σ_x^2 is essentially energy in dx/dt divided by the energy in x or the L^2 norm squared of the derivative of x

divided by the L^2 norm of x . Now, we have the answer: why we ran into a problem for $\phi(t)$? As you can see $\phi(t)$ is discontinuous so, when its derivative is considered, there are impulses in the derivative and impulse is not square integrable. Therefore, the numerator of this quantity diverges off. You look at it from that perspective; the moment we have a discontinuous function, we have an infinite frequency variance and there we are with this note, then we realize that if we want to get some meaningful uncertainty, some meaning bound, we must at least consider continuous function and we shall proceed to build on this concept further in the next lecture.

Thank you
