## **Evaluating and Bounding $\sigma_t^2$ and $\sigma_\omega^2$**

A warm welcome to the 19<sup>th</sup> lecture, on the subject of Wavelets and Multirate digital signal processing. In this lecture we shall go further on the uncertainty product or the time bandwidth product, as we called it in the previous lecture to proceed, to evaluate and to bound it. To put certain fundamental limits on it and then, to see how close we can get to those limits. Therefore, I have titled the lecture today as evaluating and bounding  $\sigma_t^2$ ,  $\sigma_\omega^2$ .

To put the discussion in perspective, let us recall very briefly what we did in the previous lecture. You will recall that, we had talked about these quantities  $\sigma_t^2$ ,  $\sigma_\omega^2$ . We are also noticed that this product,  $\sigma_t^2 \sigma_\omega^2$  is a very strong invariant. It is invariant to translation, it is invariant to modulation both in time, translation in time, modulation in time. It is invariant to multiplication of the dependent variable by a constant or scaling the dependent variable or in another words multiplying the function by a constant. Most interesting of all is that, it is invariant to a scaling of the independent variable that is striking.

So, you see ultimately what is left is just the shape, the time bandwidth product is the direct function of the shape. The shape can then get compressed or expanded, it can get scaled in the vertical direction, it can be shifted, it can be modulated by an  $e^{j\omega t}$  kind of term rotating complex number or a phaser. All these do not affect the time bandwidth product,  $\sigma_t^2 \sigma_\omega^2$  as we called it. Now, our objective today is to ask a very important question, which lies at the heart as I said of Wavelets and Multirate digital signal processing, namely how small can we make this product.

Let us put down the question first.

(Refer Time: 03:32)

Essentially, how small can the time bandwidth product be? And once again, we need to emphasize a couple of points, why are we talking about the time bandwidth product instead of just the time variance or the frequency variance. We must understand that making the time variance small or the frequency variance small is not a difficult job at all. In fact one can do it by scaling the independent variable. If you compress a function in time, the time variance is compressed by the square of that factor. If you compress a function in frequency the frequency variance is compressed by the square of that factor.

So, compressing in time or frequency separately is not a difficult job at all. In fact, the problem is that, when you compress in one domain, you are expanding in the other domain by the same factor. There is a cancellation effect as far as the time bandwidth product goes. So, compressing or expanding a function does not change its time bandwidth product, but it definitely changes the time variance and the frequency variance individually, this is what we saw in the previous lecture. In that sense physically what it means, is that nothing stops you from narrowing down as much as you desire in one of the domains. If you desire to focus on a small region of time, you can do it on as small region of time as you desire.

If you focus on certain region of frequency you can make that region of frequency on which you focus as small as you desire, there is no problem. So, focusing in one domain is not a problem, you can do it as much as you desire. The problem is focusing in both

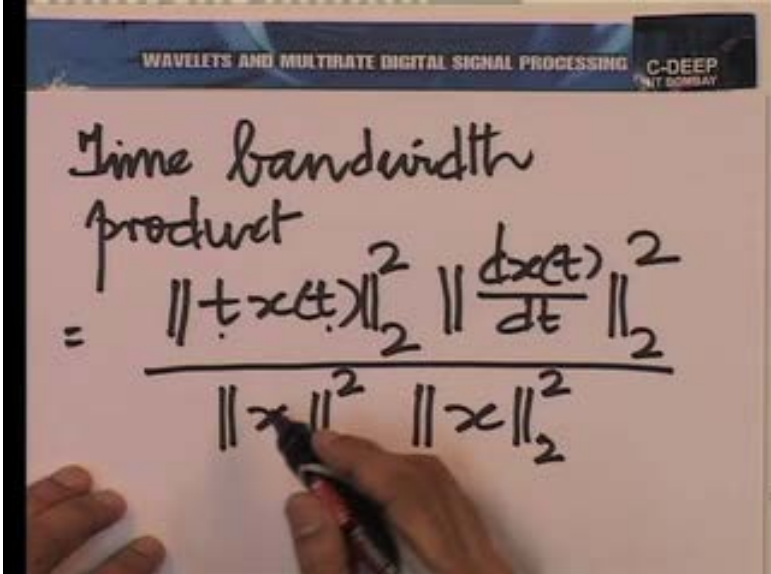

the domains together, any tool in that we use, by tool I mean a function used for analysis, any tool that we use as a time bandwidth product essentially based on its shape. So, when you use the same shape, you are bound by that number no matter how much you squeeze or expand. You are not going to be able to focus in both the domain simultaneously in fact, by focusing in one domain you are going to compromise on your ability to focus in the other. This is the general tussle as we said between time and frequency.

Now, the next natural question to ask is, how small can we make this tussle? If  $\sigma_t$  or  $\sigma_\omega$  squared could have been 0 for example, could have been it will be wonderful, nothing need it to be done. You could make any of them as small as you desire and the other one as small as you desire too. So, you could focus in two domains simultaneously. But as I said, nature does not allow this and it is the fundamental property of nature, that is does not allow this. What we are now going to answer is, what is the lower bound on this product meaning, to what extent no matter what tools you have can you really focus in both the domains together.

So, what is the ideal towards which we must derive and why is it that, we have a fundamental limitation to work with which always forces a challenge before us. Anyway to answer that question, let us recall some of the expressions that we had derived in the previous lecture. We had looked at an expression for the time bandwidth product based on entirely time domain quantities and let us put that expression down clearly once again.

We had shown that the time bandwidth products without loss of generality, can be written ultimately as follows. It is the  $L^2$  norm of  $t \times t$  the whole squared times the  $L^2$  norm of the derivative, again the whole squared divided by the  $L^2$  norm of  $x$  squared multiplied by the same. So, in other words you could write  $L^2$  norm of  $x$  raised the power of 4, if you like by combine these two terms. Anyway I am just writing them separately to emphasize a, this is associated with this and this with this notionally.

(Refer Slide Time: 08:30)

The image shows a whiteboard with handwritten text and a mathematical formula. At the top, there is a blue banner with the text "WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING" and "C-DEEP IIT BOMBAY". The main text on the whiteboard is "Time Bandwidth Product" written in cursive. Below it, the formula is written as:

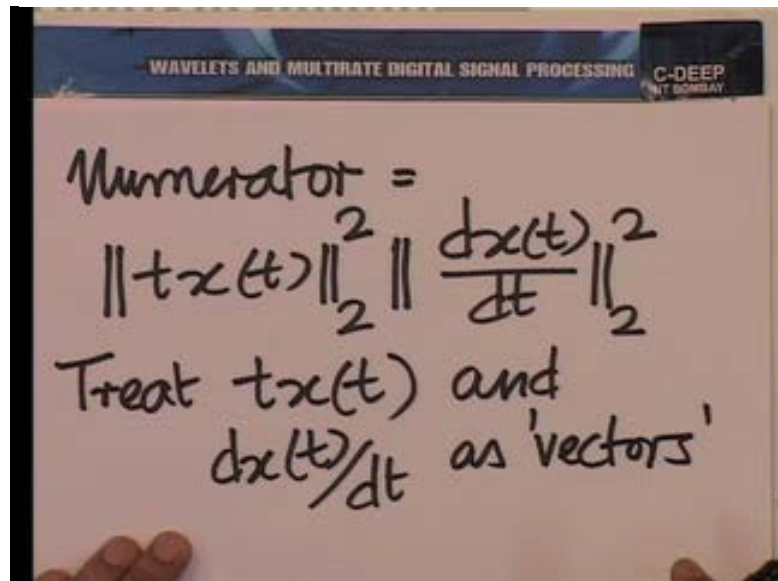

$$= \frac{\|t \cdot x(t)\|_2^2 \left\| \frac{dx(t)}{dt} \right\|_2^2}{\|x\|_2^2 \|x\|_2^2}$$

A hand is visible at the bottom of the whiteboard, holding a black marker and pointing towards the denominator of the formula.

Now, I must also again mention the slight abuse of notation here, when we write  $t$  times  $x$ , we are referring to the whole function as an object and not to a specific value of  $t$ , the same holds here. Anyway this was just to recall what we did yesterday and remember we had done this after doing a little bit of preparation on the function so to speak. Having noted the translation in time and in frequency has no effect on the time bandwidth product we had said. We could shift the function in time so that, it is centered in time. Subsequently, we can shift it in frequency without affecting the time function so that, it is centre in frequency. In all this, the time bandwidth product has not changed.

So, here we have a function which has been assumed to be centered in time and frequency and now, we are working with that function and this is without any loss of generality. Anyway coming back then to the calculation of these quantities, let us once again gives a vectorial interpretation to this. Now, you see look at the numerator, the numerator is a product of two squared norms, let us focus our attention on the numerator.

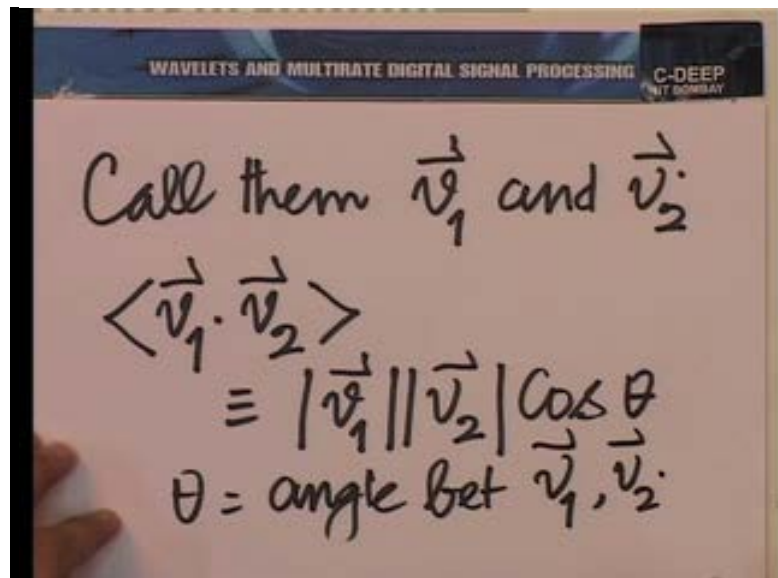

(Refer Slide Time: 11:07)

A handwritten slide from a presentation. The slide has a blue header with the text "WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING" and "C-DEEP IIT BOMBAY". The main content is written in black ink on a white background. It starts with "Numerator =", followed by the equation  $\|tx(t)\|_2^2 \left\| \frac{dx(t)}{dt} \right\|_2^2$ . Below this, it says "Treat  $tx(t)$  and  $dx(t)/dt$  as 'vectors'".

Numerator =  
 $\|tx(t)\|_2^2 \left\| \frac{dx(t)}{dt} \right\|_2^2$   
Treat  $tx(t)$  and  $dx(t)/dt$  as 'vectors'

So, numerator here is the norm of  $t \times t$ , the whole squared multiplied by the norm of  $dx/dt$  the whole squared in  $L^2$ . Now, let us take recourse to a very fundamental principle that we know in vector analysis. Treat  $t \times t$  and  $dx/dt$  as vectors, as we often do generalized vectors.

(Refer Slide Time: 11:58)

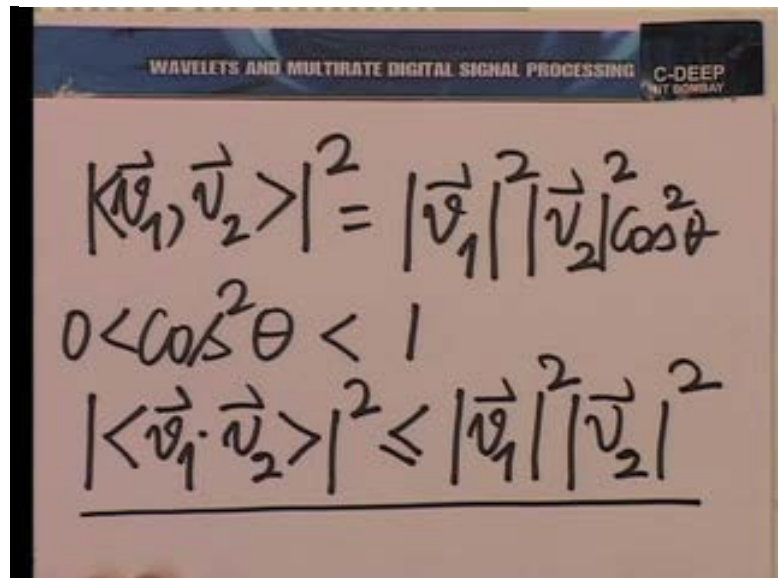

A handwritten slide from a presentation. The slide has a blue header with the text "WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING" and "C-DEEP IIT BOMBAY". The main content is written in black ink on a white background. It starts with "Call them  $\vec{v}_1$  and  $\vec{v}_2$ ", followed by the inner product equation  $\langle \vec{v}_1, \vec{v}_2 \rangle \equiv |\vec{v}_1| |\vec{v}_2| \cos \theta$ . Below this, it says " $\theta = \text{angle bet } \vec{v}_1, \vec{v}_2$ ".

Call them  $\vec{v}_1$  and  $\vec{v}_2$   
 $\langle \vec{v}_1, \vec{v}_2 \rangle \equiv |\vec{v}_1| |\vec{v}_2| \cos \theta$   
 $\theta = \text{angle bet } \vec{v}_1, \vec{v}_2$

So, let us call them  $v_1$  vector and  $v_2$  vector. Now, if we recall a basic principle of inner products. The inner product of  $v_1$  with  $v_2$  is essentially of the form, the magnitude of  $v_1$  times the magnitude of  $v_2$  times the cosine of the angle between  $v_1$  and  $v_2$ , theta is

the angle between  $v_1$  and  $v_2$ . And therefore, it is obvious in very low dimensional spaces which can be taken to higher dimensional spaces also, that if you consider the magnitude squared of the dot product

(Refer Slide Time: 13:11)

The image shows a slide with handwritten mathematical equations. At the top, there is a header that reads "WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING" and "C-DEEP IIT ROORKEE". The main content consists of three lines of handwritten text:

$$|\langle \vec{v}_1, \vec{v}_2 \rangle|^2 = |\vec{v}_1|^2 |\vec{v}_2|^2 \cos^2 \theta$$
$$0 < \cos^2 \theta < 1$$
$$|\langle \vec{v}_1, \vec{v}_2 \rangle|^2 \leq |\vec{v}_1|^2 |\vec{v}_2|^2$$

The final inequality is underlined.

Let me use the dot product notation. It is the product of the magnitude squared of  $v_1$  and  $v_2$  multiplied by  $\cos^2 \theta$  and  $\cos^2 \theta$  is always less than 1 in fact, between 0 and 1. Here of course, we are talking about  $\theta$  real and that is the interpretation which we always have, even if we are talking about complex functions, the angle here is assumed to be real. You see what it means therefore, is that the modulus of the dot product squared is always less than or equal to the modulus of  $v_1$  squared times, the modulus of  $v_2$  squared.

This is a very simple, but a very important principle and in fact, this principle can be generalized to these generalized vectors that we are talking about, functions viewed as vectors. In fact, this is a very important property or a very important theorem in functional analysis, it is often called the Cauchy Schwarz inequality. It says and let me write that down in formal language, it says the inner product the magnitude squared of the inner product of two functions.

(Refer Slide Time: 15:08)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP  
NT DOMBAY

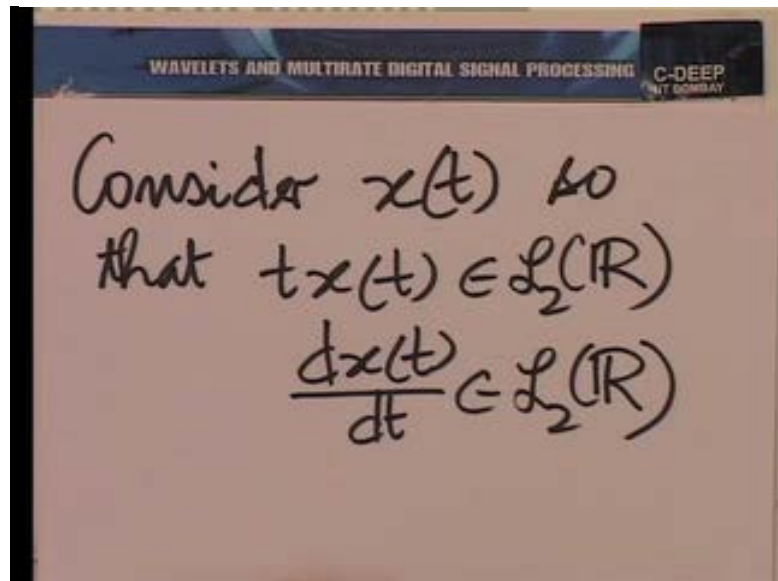

$$\langle f_1, f_2 \rangle \quad f_1, f_2 \in L_2(\mathbb{R})$$
$$|\langle f_1, f_2 \rangle|^2 \leq \|f_1\|_2^2 \|f_2\|_2^2$$

Cauchy-Schwarz inequality

So, let assume that two functions  $f_1$  and  $f_2$  and  $L_2 \mathbb{R}$ . The magnitude squared of the dot product of  $f_1$  and  $f_2$  is less than equal to the product of the squared norms in  $L_2 \mathbb{R}$  of  $f_1$  and  $f_2$ . The Cauchy Schwarz inequality, as it is often known. Now this vectorial interpretation makes this property obvious, but one can also prove this formally, in functional analysis without taking we course to this visualization in the language of vectors.

However, since it is not our objective to review this basic concept from functional analysis, I mean to give a detail proof. We shall give it this vectorial interpretation and be satisfied. So, we will take the Cauchy Schwarz inequality as true and proceed from there. Now, please remember that we are assuming in this process, that these functions belong to  $L_2 \mathbb{R}$ . So let us go back to our uncertainty time bandwidth product.

(Refer Slide Time: 17:02)

Consider them  $x(t)$  so that,  $tx(t)$  belongs to  $L_2(\mathbb{R})$  and  $\frac{dx(t)}{dt}$  belongs to  $L_2(\mathbb{R})$ . What if they do not for example, we took the very simple case of a rectangular pulse, a while ago.

(Refer Slide Time: 17:46)

We saw that if we consider this function, not true for this function. Because  $\frac{dx(t)}{dt}$  does not belong to  $L_2(\mathbb{R})$  here, why so?  $\frac{dx(t)}{dt}$  has two impulses.

(Refer Slide Time: 18:23)

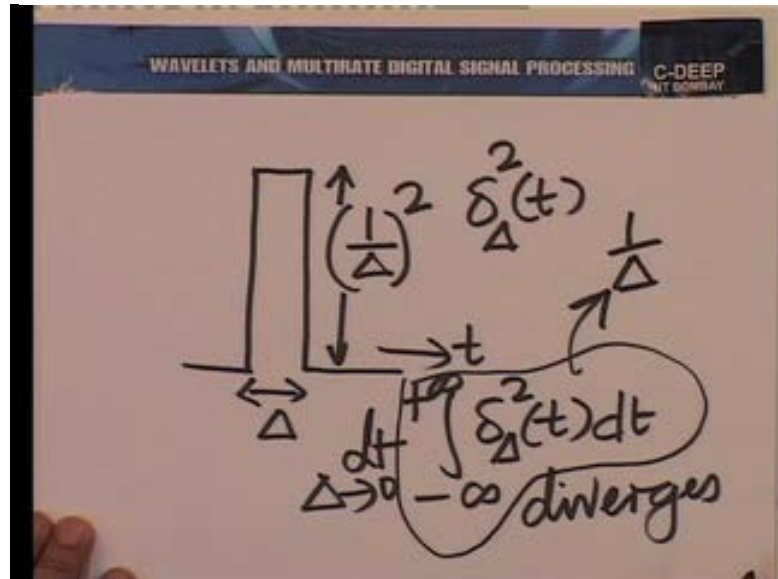

$dx(t)/dt$  would have an appearance like this, an impulse there and a downward impulse at the end of the pulse, this is what  $dx(t)/dt$  would look like here. And impulses are not square integrable, impulses do not have finite energy. I shall just spend a minute in justifying this, because we have so far been informally saying it we also proved this indirectly by looking at the frequency variance in this case. But we also must understand the direct proof here. After all, what is an impulse?

(Refer Slide Time: 19:09)

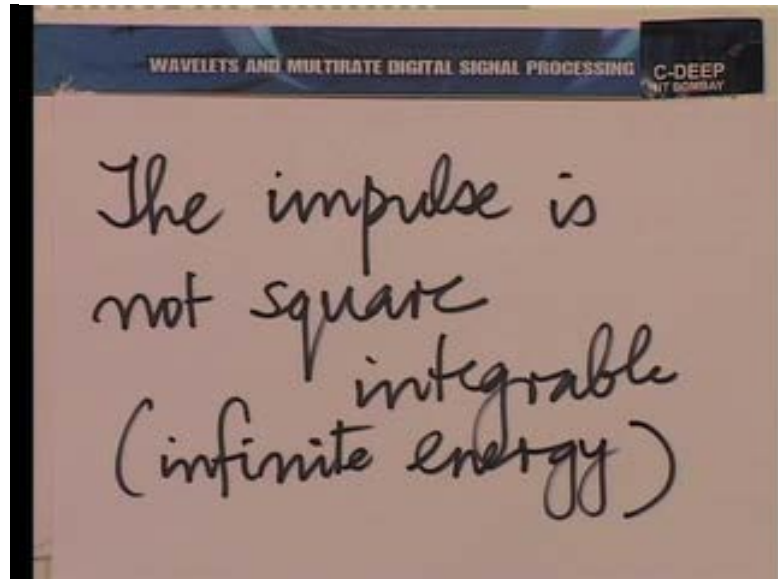

An impulse is a limiting case of this, an object which lies on a width of  $\Delta$  with a height of  $1/\Delta$ . This is  $\delta_\Delta(t)$ , if you please and an impulse or a unit impulse to be more precise is essentially something like a limit, as  $\Delta$  tends to 0 of  $\delta_\Delta(t)$ . Now, when you take the square of this so,  $\delta_\Delta(t)^2$ , it is look like this.

(Refer Slide Time: 20:18)

And now, if you take the integral of  $\delta_\Delta(t)^2$  overall  $t$ , then it diverges when you take the limit. In fact, this integral essentially  $1/\Delta$  and this is divergent. This limit does not exist. Therefore, the impulse is not square integrable. We must make a note of this as an important conclusion. Infinite energy, it contains infinite energy. And that is manifested also in calculating the frequency variance for this rectangular parts, anyway that a part. We have now agreed that, if that is the case, anyway that lower bound does not arise, where these quantities diverge in spite of  $x$  belonging to  $L^2(\mathbb{R})$ . Remember, since  $x$  belongs to  $L^2(\mathbb{R})$  in the beginning, we had this denominator.

(Refer Slide Time: 21:05)

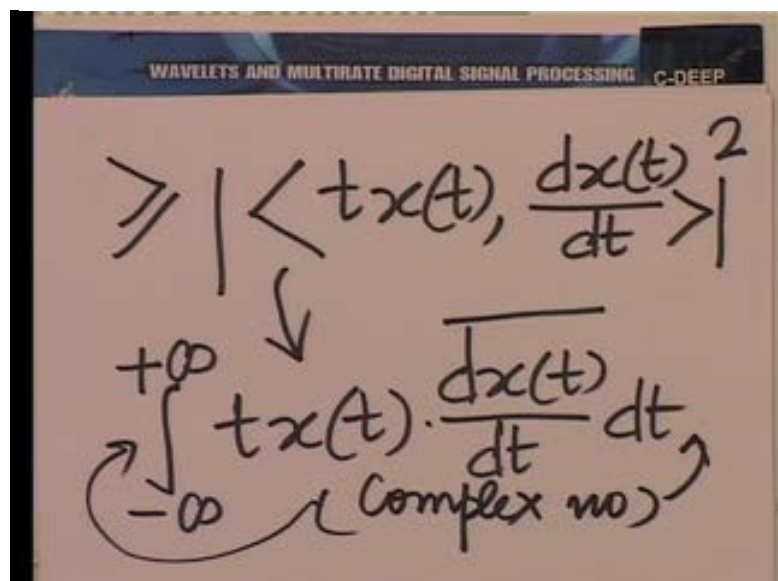

So you had this denominator right in the beginning, norm  $x^2$  in  $L^2 \mathbb{R}$  to the power 4 effectively and this is guaranteed to be finite, because we have confined ourselves to  $x^2$  into  $L^2 \mathbb{R}$ . So, if this is an  $L^2 \mathbb{R}$ , the denominator is finite and positive obviously, otherwise it does not make sense I mean, you are not going to take a trivial function. So, for a nontrivial function this is strictly positive and finite. And then if anyone of these is infinite, there is no question of finding a lower bound, it anywhere you know is the worst possible case that you can have. So, it is no harm then that we have in considering finite quantities in the numerator. So, with that little remark about our restriction, let us take them to be finite and proceed.

And use the Cauchy Schwarz inequality. So, using Cauchy Schwarz inequality what do we have? Now, we use it the other way, what we have in the numerator is the norm squared in  $L^2 \mathbb{R}$  of  $t \times t$  times the norm squared of  $dx \ t \ dt$  in  $L^2 \mathbb{R}$  and from Cauchy Schwarz inequality we go further.

(Refer Slide Time: 23:07)

(Refer Slide Time: 23:54)

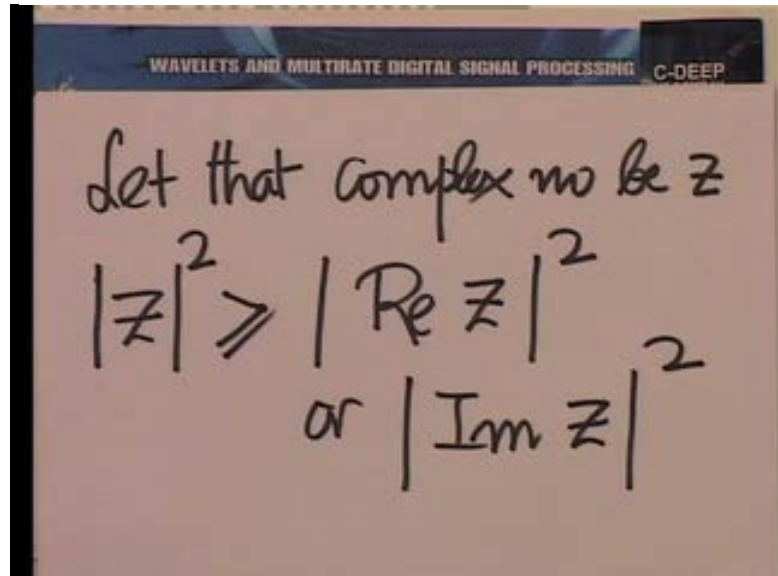

This must be greater than or equal to the magnitude of the dot product squared. Let us write this down, this dot product is essentially the following integral.

Remember we need not confined ourselves to real functions, we should not because we are allowing a modulation in time. So, you must allow complex functions here, we have of course, centered the function that is the different issue. We need to center them that we have done. Now, let us essentially look at this integral a little more carefully. Now,

we are talking about this as an entire complex number. This whole thing is the complex number from here to here, if you take the magnitude squared of a complex number.

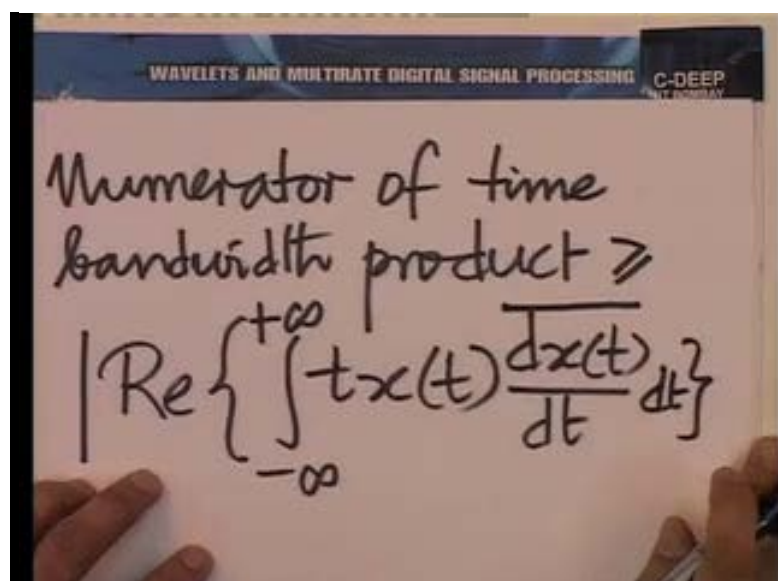

(Refer Slide Time: 25:35)

Let that complex no be  $z$   
 $|z|^2 \geq |Re z|^2$   
or  $|Im z|^2$

So, let that complex number be  $Z$ . It is obvious that the modulus squared of  $Z$  is greater than the modulus or greater than or equal to in general, the modulus squared of the real part of  $z$  and we use that property here. Of course, a same thing holds good for the imaginary part two, but we are interested in the real part here.

(Refer Slide Time: 26:20)

Numerator of time  
bandwidth product  $\geq$   
 $|Re \left\{ \int_{-\infty}^{+\infty} t x(t) \frac{dx(t)}{dt} dt \right\}|$

So, in particular we have the numerator of the time bandwidth product is greater than or equal to modulus, real part of this integral. The complex conjugate is above this entire thing. So, this is what we have here. Now, a remark about this part this complex conjugate, we are taking the derivative of a possibly complex function  $x$  of  $t$  with respect to the real variable  $t$ . So, the complex conjugate of  $\frac{dx}{dt}$  is also the derivative of the complex conjugate of  $x$ , what I am saying in effect is that. Because  $t$  is a real variable  $\overline{\frac{dx}{dt}}$  is also  $\frac{d\bar{x}}{dt}$  and I should employ that in this expression first.

(Refer Slide Time: 27:46)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP  
M.T. BOMBAY

Because  $t$  is real

$$\overline{\frac{dx(t)}{dt}} = \frac{d\bar{x}(t)}{dt}$$

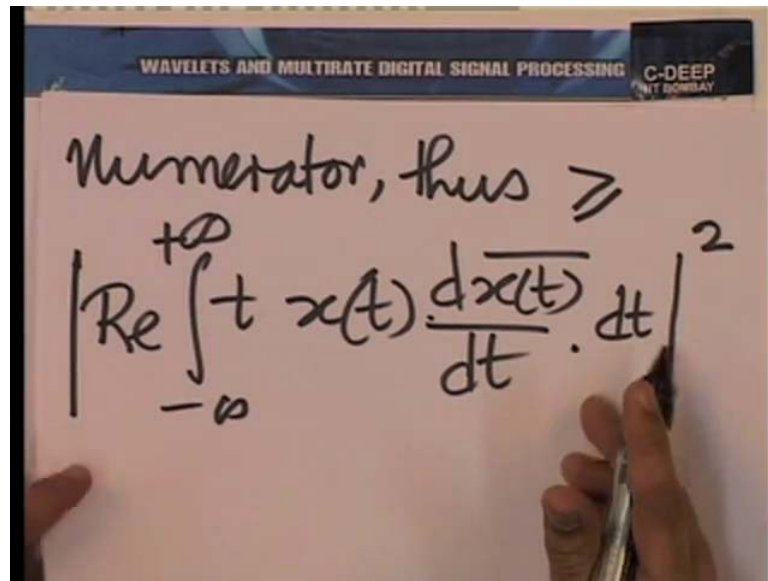

(Refer Slide Time: 28:11)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP  
M.T. BOMBAY

Numerator of time bandwidth product  $\geq$

$$\left| \operatorname{Re} \left\{ \int_{-\infty}^{+\infty} t x(t) \overline{\frac{dx(t)}{dt}} dt \right\} \right|^2$$

(Refer Slide Time: 28:20)

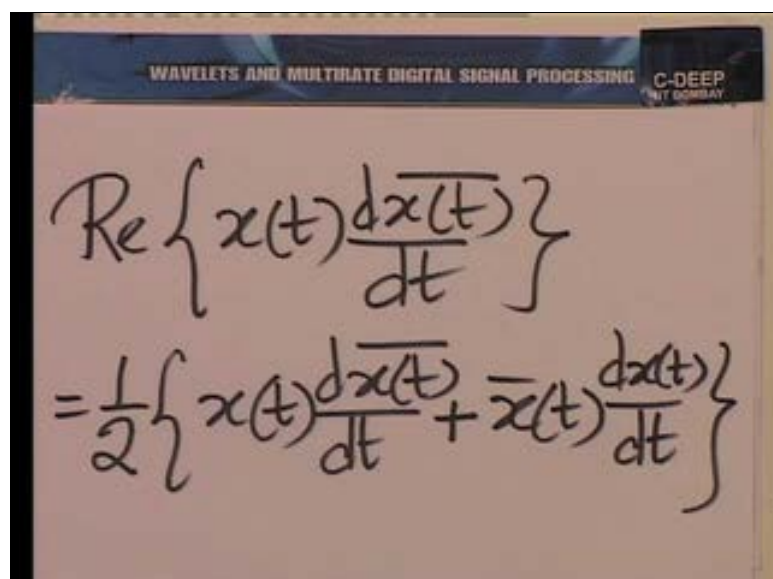

Numerator, thus  $\geq$

$$\left| \operatorname{Re} \int_{-\infty}^{+\infty} x(t) \frac{d\overline{x(t)}}{dt} dt \right|^2$$

So, this quantity now is equal to. The modulus of the real part of the following the real part operates on the whole integral. And now we again, look at the real part. You see the real part is operating on an integral with respect to  $t$ ,  $t$  is a real variable. So, the element of integration is real this is a real function this is possibly a complex function. So, the real part can be taken right inside the integral and brought to operate on this only, a rest of it does not require you to say real part explicit.

(Refer Slide Time: 30:18)

$$\operatorname{Re} \left\{ x(t) \frac{d\overline{x(t)}}{dt} \right\}$$
$$= \frac{1}{2} \left\{ x(t) \frac{d\overline{x(t)}}{dt} + \overline{x(t)} \frac{dx(t)}{dt} \right\}$$

So, this expression is equal to integral from minus to plus infinity  $t$  times, the real part of  $x(t) \frac{d}{dt} \overline{x(t)}$  the whole squared. And now, we take note of this, how do we calculate the real part of a complex function, complex number in general. By adding the complex number and its conjugate and dividing by 2. So, essentially what we are saying is real part of  $x(t) \frac{d}{dt} \overline{x(t)}$  is half  $x(t) \frac{d}{dt} \overline{x(t)}$  plus the complex conjugate of this. And what is that complex conjugate, it is  $\overline{x(t) \frac{d}{dt} \overline{x(t)}}$  simple. And now we can see a product rule has been employed here, essentially what we have here is the derivative of  $x(t)$  into  $\overline{x(t)}$  that is an important observation.

(Refer Slide Time: 31:05)

The image shows a whiteboard with handwritten mathematical equations. At the top, there is a header that reads "WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING" and "C-DEEP" with "KIT DOWRY" below it. The main content of the whiteboard consists of two lines of equations:

$$= \frac{1}{2} \frac{d}{dt} \left\{ x(t) \overline{x(t)} \right\}$$

$$= \frac{1}{2} \frac{d}{dt} |x(t)|^2$$

So, here this is equal to half  $\frac{d}{dt}$  of  $x(t) \overline{x(t)}$  and  $x(t) \overline{x(t)}$  is in fact the modulus of  $x(t)$  the whole squared, a very beautiful observation. And now, we will put back that observation into the time bandwidth product.

(Refer Slide Time: 31:45)

$$\begin{aligned} &= \frac{1}{2} \frac{d}{dt} \left\{ x(t) \overline{x(t)} \right\} \\ &= \frac{1}{2} \frac{d}{dt} |x(t)|^2 \end{aligned}$$

So Therefore, the numerator of the time bandwidth product is thus greater than or equal to modulus, half integral from minus to plus infinity  $t$  times  $d dt \text{ mod } x t$  squared  $d t$  and this the whole squared. Let us take a minute to reflect on this, how do we evaluate this integral? Well that is easy. We can evaluate this integral by parts and to evaluate by parts we must first make the integral indefinite.

(Refer Slide Time: 32:54)

$$\begin{aligned} &\int_{-\infty}^{+\infty} t \frac{d}{dt} |x(t)|^2 dt \\ &= t |x(t)|^2 \Big|_{-\infty}^{+\infty} - \int_{-\infty}^{+\infty} |x(t)|^2 dt \end{aligned}$$

So, let us simply consider the indefinite integral corresponding to this. Clearly this is, this term minus this term. And now we can substitute the limits. So, we can put back the

limits of minus to plus infinity here and put this from minus to plus infinity first, and then this from minus to plus infinity as well. Now, let us focus our attention on each of these terms individually. Let us take the first term,  $t$  times  $\text{mod } x$   $t$  the whole squared, evaluated at plus infinity and then from it subtract evaluated at minus infinity.

(Refer Slide Time: 34:11)

So, let us focus our attention on  $t \text{ mod } x$   $t$ . The whole squared evaluated at the two limits and subtracted. Now, we have agreed that  $t$  squared  $\text{mod } x$   $t$  squared  $dt$  from minus to plus infinity is finite, we have agreed on that. We said, if that is not true anyway we have an infinite bound, there is no question of lower bounding them, it is a worst case that we can deal with. So, if this is finite obviously, you see if the integral must be finite the function must decay towards 0 at the ends. If the function does not decayed to 0 as in tactically as you go toward plus infinity and as you go towards minus infinity, you can see that there is going to be an infinite range over which the function has a finite positive value, which would make the integral diverge. So, in order that is integral converge  $t$  squared  $\text{mod } x$   $t$  squared  $dt$ , the function  $t$  squared  $\text{mod } x$   $t$  squared must decay as  $t$  tends to plus infinity and minus infinity let us make that observation.

(Refer Slide Time: 35:45)

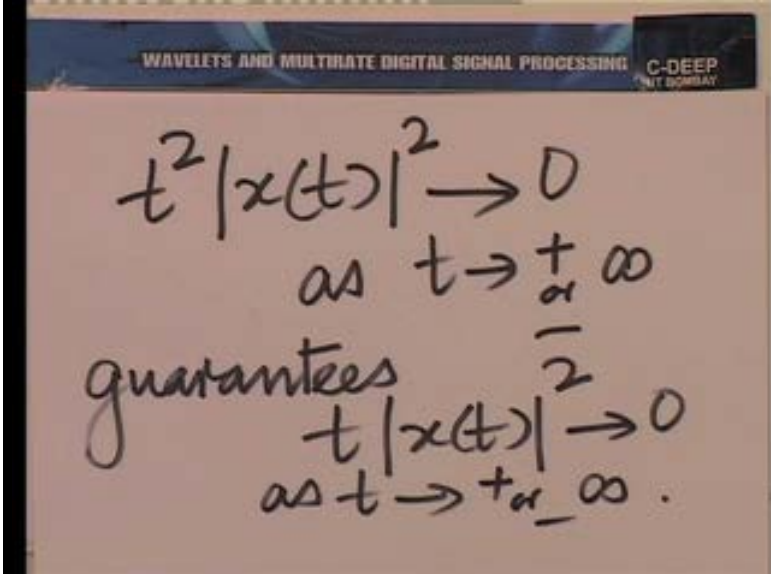

In order that this integral converge.  $t$  squared mod  $x$   $t$  squared tends to 0, as  $t$  tends to plus infinity and  $t$  tends to minus infinity. Now, it is also true that for  $t$  greater than 1 and of course, as  $t$  tends to infinity  $t$  is definitely going to be greater than 1.

(Refer Slide Time: 36:25)

So, for  $t$  greater than 1 and certainly so and I am talking about  $t$  squared actually, or mod  $t$ . Certainly, so as mod  $t$  tend to infinity  $t$  tends to plus infinity or minus infinity. You must have  $t$  squared greater than  $t$ , what this means is that.

(Refer Slide Time: 37:01)

The slide shows the following handwritten text:

$$t^2 |x(t)|^2 \rightarrow 0$$

as  $t \rightarrow +\infty$   
or  $-\infty$

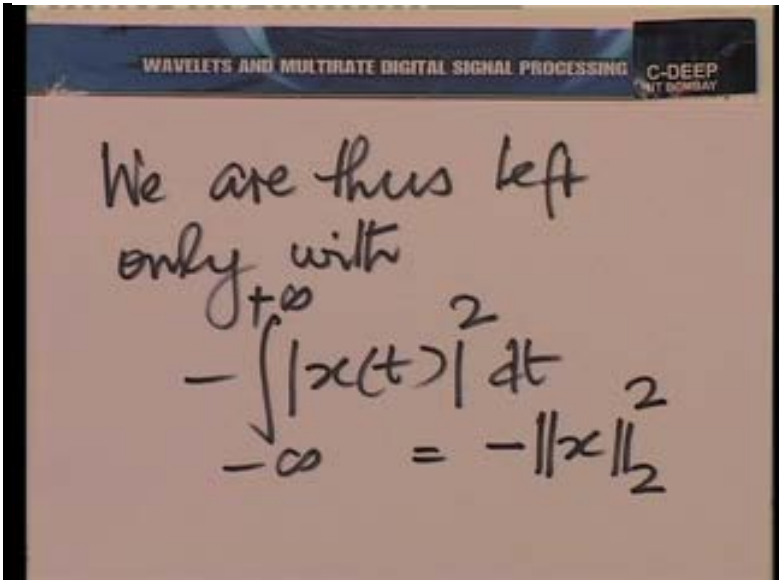

guarantees

$$t |x(t)| \rightarrow 0$$

as  $t \rightarrow +\infty$   
or  $-\infty$ .

$t^2 |x(t)|^2 \rightarrow 0$ , as  $t$  tends to plus or minus infinity guarantees  $t |x(t)| \rightarrow 0$  as  $t$  tends to plus or minus infinity and therefore, that first term has vanished.

(Refer Slide Time: 37:44)

The slide shows the following handwritten text:

We are thus left only with

$$-\int_{-\infty}^{+\infty} |x(t)|^2 dt = -\|x\|_2^2$$

So, we are left only with the second term and the second term is very familiar to us. In fact this is minus the norm of  $x$  in  $L^2 \mathbb{R}$  the whole squared so simple. And therefore, we have a very beautiful conclusion here.

(Refer Slide Time: 38:26)

$$\begin{aligned} \text{Numerator} &\geq \left| \frac{1}{2} (-\|x\|_2^2) \right|^2 \\ &= \frac{1}{4} \|x\|_2^2 \|x\|_2^2 \end{aligned}$$

We are saying the numerator is always greater than or equal to modulus half into minus the norm of  $x$  in  $L^2 \mathbb{R}$  the whole squared, the whole squared, which is one-fourth times this, times this.

(Refer Slide Time: 39:20)

$$\begin{aligned} \text{Thus: Time bandwidth product} &\geq \frac{\frac{1}{4} \|x\|_2^4}{\|x\|_2^4} \\ &= \frac{1}{4} \\ &= 0.25 \end{aligned}$$

And therefore, overall the time bandwidth product is greater than equal to one-fourth norm  $x$  in  $L^2 \mathbb{R}$  to the power 4 divided by norm  $x$  in  $L^2 \mathbb{R}$  to the power 4, which is one-fourth a very fundamental conclusion. The time bandwidth product can never be less than one-fourth 0.25. So, 0.25 is the very lowest value of the time bandwidth product that

you can get. And what we concluded here has nothing to do with the tools available at a particular time, with the technology available at a particular time or with the machines and the political situation whatever, it is fundamental to signal processing.

In fact, so fundamental is this result that we have derived that, in different manifestations it is seen in different subjects. What we call the uncertainty limit in physics is just another version of this. People talk about the inability to locate position and momentum simultaneously. Actually, it is just another version of this. I shall just give a small hint as to how you might connect this idea of time bandwidth product to the concept of position momentum uncertainty. And to do that actually, we will go back to the expression for the time bandwidth product that we had derived.

(Refer Slide Time: 41:34)

You see you noticed that, we will show that essentially the time bandwidth product relates to a time variance. You know the time variance relating to the norm of  $t x t$  the whole squared. And you are assuming the object is centered. Now, think of  $x t$  as descriptive of an object, remember that we are talked about a one dimensional mass. Now, here we talking about  $x t$  then as the kind of mass distribution of the object or other if not mod it is if not  $x t$  is really mod  $x t$  squared, which is like a mass distribution of that object.

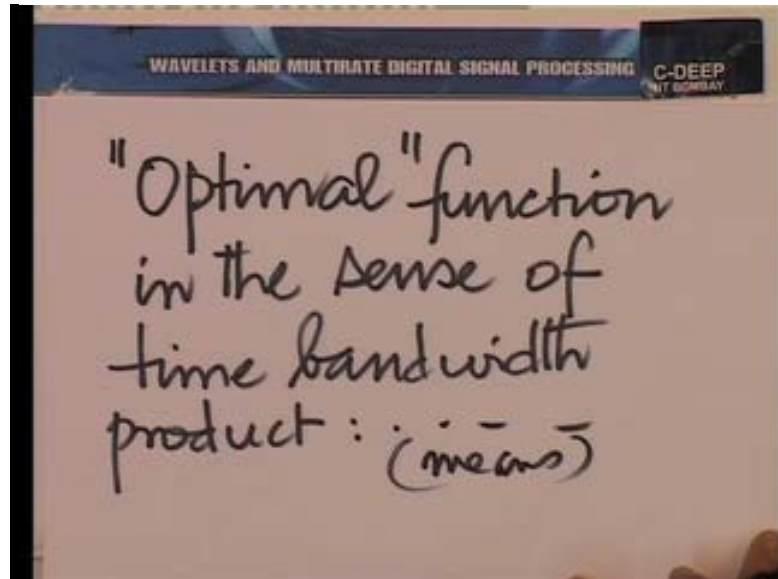

So division the denominator part is essentially a normalization make the object unit mass if you like. But here, in the time variance the numerator is indicative of the uncertainty in

position. What is the variance of the object as far as it is spread around the center is concerned, that is what the time variance tells you. Now, if you look at the other term there the frequency variance. So, time variance involves this, frequency variance involves this. And you know involving this, the derivative of  $x(t)$  with respect to  $t$  now,  $x'(t)$  or  $\text{mod } x(t)^2$  as I said is indicative of in some sense the presence of that mass or that body on  $t$ . So,  $d x(t) / d t$  is indicative of the momentum of that body, the change with respect to time.

So, here in some sense the change, the it is indicative of a change. So, in a broad sense you can see the connection between position and momentum, uncertainty in where it is in, uncertainty in how it changes. Let me not tell too much further on this, to interpret precisely how this is the uncertainty principle in physics, I think we should leave it to a physicist a person who specializes in that. But this is what have just given you is an intuitive indication that is all. However, is just to bring out the various meanings that this time bandwidth product or this uncertainty limit has. It has meanings in different subjects.

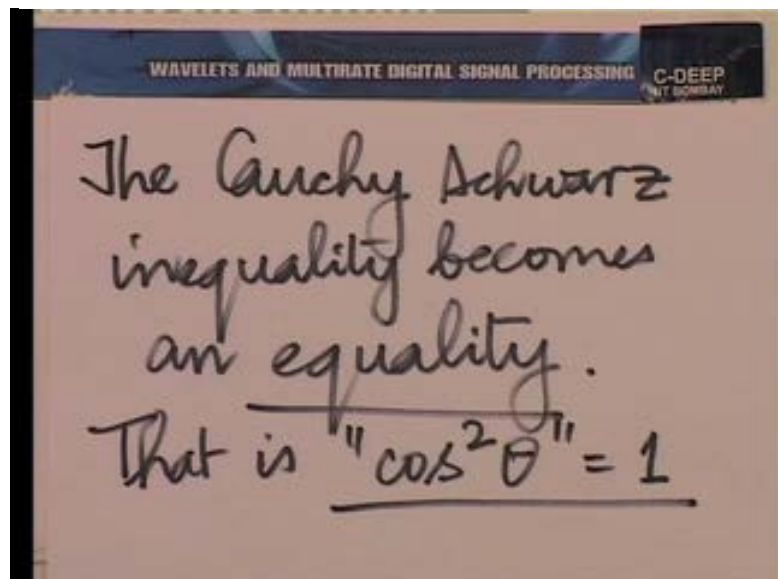

Anyway coming back to a subject with which, we are deal this is the whole basis on the subject of wavelets often that matters a time frequency methods, what it tells us is that no matter what we do. We are not going to get any function which has finite energy and which can be confined beyond the certain point in the two domains time and frequency simultaneously, that is bad news. What was worse is that, if looked at the Haar case, it is not confined at all the time bandwidth product was infinity. So, now we naturally ask the next question is there a function which gives us this 0.25 or is it something that we should never seek, that is not very difficult to answer. In fact that can be answered again by using a vectorial interpretation, when does the numerator become equal in the Cauchy Schwarz inequality to the expression that we derived.

(Refer Slide Time: 46:21)

So, the optimal function in the sense of time bandwidth product means.

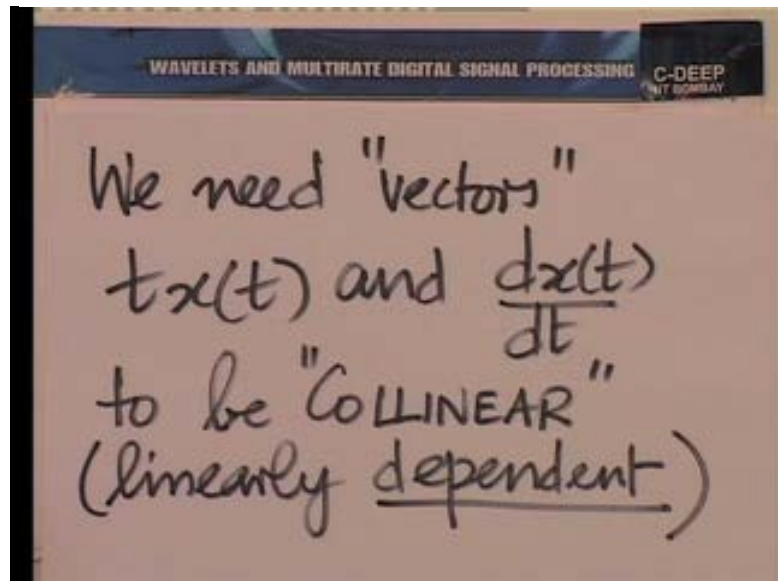

(Refer Slide Time: 46:38)

The Cauchy Schwarz inequality becomes an equality. Now, where would that become an equality, it would become an equality if the Cos squared theta term is 1, that is the cos squared theta term is 1. And what you mean by the Cos squared theta term been 1, what really is theta? Theta is an angle between these two so called vectors,  $t \times t$  and  $dx \ t \ dt$ . If you want the angle to be such that, Cos squared is 1, these two vectors must be collinear, they must be along the same line so to speak.

(Refer Slide Time: 47:54)

So therefore, in the language of functions we need the vectors, so called vectors  $t x t$  and  $dx t dt$  to be collinear one dimensional. What you mean by them been collinear, they must be linearly dependent. And what you mean by them been linearly dependent, any of them must be a multiple of the other.

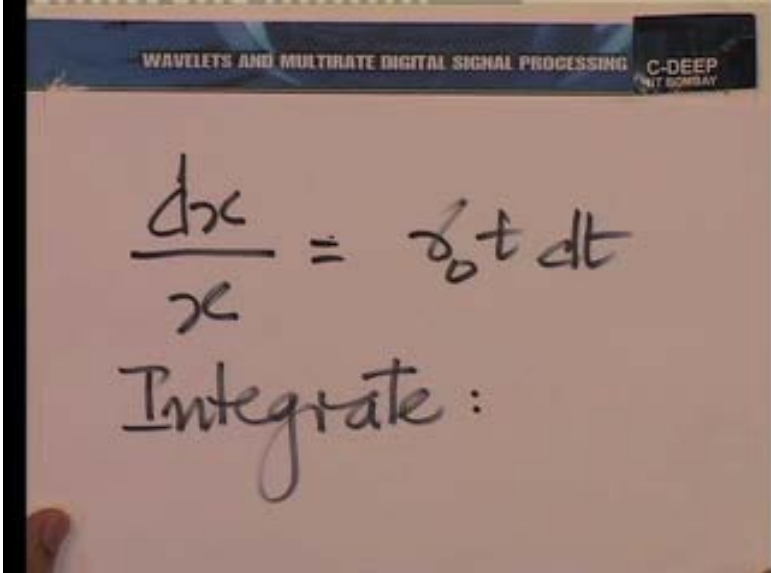

(Refer Slide Time: 48:44)

In other words  $dx t dt$  is some constant, let us call that constant  $\gamma_0$  times  $t x t$ . The solution of this equation would give us, the so called optimal function, so we solve this.

How do we solve it? By a simple change of the or this the redistribution of the derivative.

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP  
IIT BOMBAY

$$\frac{dx}{x} = \gamma_0 t dt$$

Integrate:

So, essentially what we are saying is dx by x is equal to gamma not t dt and if I integrate.

(Refer Slide Time: 49:53)

WAVELETS AND MULTIRATE DIGITAL SIGNAL PROCESSING C-DEEP  
IIT BOMBAY

$$\int \frac{dx}{x} = \left\{ \int_0^t \frac{\gamma_0 t^2}{2} + c_0 \right\}$$

$\int \frac{dx}{x} \rightarrow \ln x$

$c_0 \rightarrow$  Const of integ

We get gamma 0 t squared by two all log natural x well we must have a constant here, a constant of integration and this is of course, log natural x. So, in other words we have log natural x is of the form gamma 0 t squared by 2 plus c 0. Let us raise both sides using the

natural base e. So, e raise the power  $\ln x$ , is e raise the power this. And therefore, we have e raise the power  $\ln x$  is thus x.

(Refer Slide Time: 50:51)

$$x(t) = c_0 e^{\frac{\gamma_0 t^2}{2}}$$

So, x of t is some constant, e raise the power  $c_0$ , this is the constant. Let us call this constant  $c_0$  tilde times e raise the power  $\gamma_0 t$  squared by 2.

(Refer Slide Time: 51:22)

$$x(t) = c_0 e^{\frac{\gamma_0 t^2}{2}}$$

$$x(t) \in L_2(\mathbb{R})$$

So, let us write down again and let us make a remark on  $\gamma_0$ . x t is of the form  $c_0$  tilde times e raise the power  $\gamma_0 t$  squared by 2. Now, you want x t to belong to  $L_2 \mathbb{R}$ .

(Refer Slide Time: 51:52)

$$|x(t)|^2 = |c_0|^2 |e^{\gamma_0 t/2}|^2$$

to be integrable

And therefore, you want  $\text{mod } x \text{ } t \text{ squared}$ , which is essentially  $\text{mod } c_0 \text{ tilde squared}$  times  $\text{mod } e \text{ raise the power } \gamma_0 t \text{ squared by } 2$  to be integrable.

(Refer Slide Time: 52:20)

Possible only  
if  $\gamma_0$  has  
a negative real  
part

Now, this is possible only if  $\gamma_0$  has a negative real part. If  $\gamma_0$  has a positive real part, this is going to be a Gaussian, so called Gaussian that grows in time, is not going to be square integrable. And therefore, we must choose  $\gamma_0$  with the negative real part and we can choose any one example of that.

(Refer Slide Time: 53:02)

So, in other words one function, which reaches the lower bound which is optimal in this sense, is with gamma 0 equal to minus 1. And there we have we can also choose c 0 tilde to be 1, because it does not matter, you scale a function a time bandwidth product is an effective.

(Refer Slide Time: 53:42)

And therefore, one optimal function in the sense of time bandwidth product, that is with time bandwidth product equal to 0.25 is the Gaussian.

(Refer Slide Time: 54:13)

A very interesting conclusion, the Gaussian is optimal. The Gaussian seems to arise in many situations it has a reason in this having noted this. We shall conclude today's lecture and proceed in the next lecture to dwell further into this is you of how close we can get to the optimal with other functions. Thank you.
