Lecture - 23
Calculation of Probability of Error (Part - 2)

Hello every one, in the last class we started discussion on probability of error calculation for different digital modulations schemes. And we actually calculated the probability of error for pulse amplitude modulation, for binary pulse amplitude modulation. And in this class we will continue our discussion, on probability of error calculation and specially try to see, how to compute probability of error for some other modulation techniques.

(Refer Slide Time: 01:37)

So, in the last class we saw that, for a binary signal set if we have 2 points at distance d from each other and if the noise variance is σ and we know that that the σ is nothing, but $\sqrt{N_0/2}$. Because, σ is the standard deviation of the noise component, in 1 dimension or dimension noise.

So, the variance σ^2 is a $N_0/2$ and then, the probability of error for this modulation will be $Q(d/2\sigma)$, while Q function is the area under the Gaussian pdf probability density function of unit variance; 0 mean unit variance. If we take Gaussian pdf of 0 mean and unit variance and take a point here then, this area is the value of the Q function at this point.

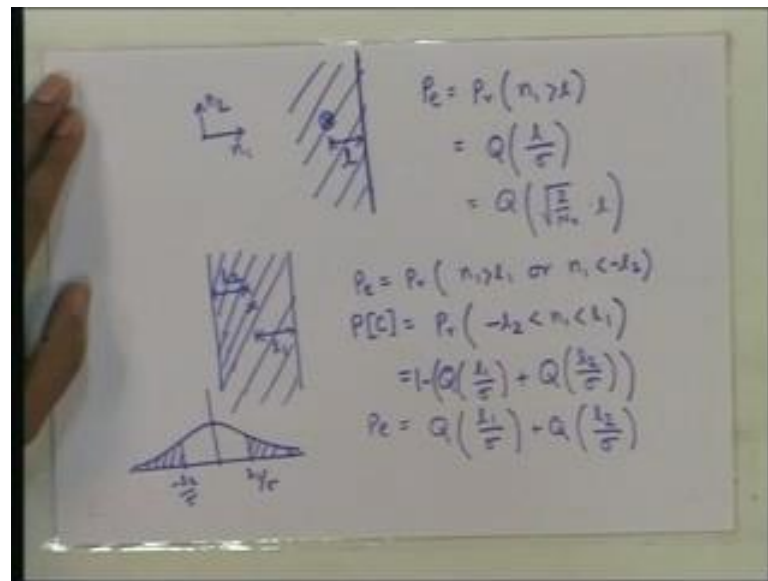

Then we have seen that, this is the probability of error for the binary modulation scheme. And we can replace σ by this and we can write this as $Q\left(\frac{d}{\sigma}\right)$ or $Q\left(\frac{d}{\sqrt{2N_0}}\right)$. For binary PAM, we can see that the 0 is here and these towards the points. So, if this distance is d , then this is $d/2$, this is $d/2$ and so the energy of the signal, each of the signal is $d^2/4$.

So, d is $2 \times \sqrt{E_s}$ and so for binary PM, we have P_e equal to $Q\left(\frac{d}{\sigma}\right)$ or $Q\left(\frac{2\sqrt{E_s}}{\sqrt{2N_0}}\right)$. And for binary FSK or any other orthogonal modulation scheme; binary orthogonal modulation scheme, binary FSK or binary orthogonal signal set, what do we know? We know that d is $\sqrt{2E_s}$ because, the signal set is like this; there 2 points here and the energy of each of these points is E_s . So, this distance is $\sqrt{2E_s}$. So, this distance d is $\sqrt{2} \times \sqrt{E_s}$ that is $\sqrt{2E_s}$. So, P_e in this case will be $Q\left(\frac{\sqrt{2E_s}}{\sigma}\right)$.

So, for any binary signal set, we can compute the probability of error, if we are able to compute the Q function value at any point and only thing we want we need to know, is the distance between the 2 points; the signal points and the noise variance. So, this is actually a fundamental component in computing the probability of error of a any signal set. This, the method of computation of probability of error for binary signal set, is a very standard technique. This will be used; the similar technique will be used in computing the other probability of error, for other modulation technique as well.

So, let us try to generalize these 2 other type of signal sets.

(Refer Slide Time: 06:36)

Let us consider 1 point in a signal set. Suppose, we have a signal set and we are considering 1 particular point and we want to find out, what is probability of error if this point is transmitted? So, there will be some other points and because of that, there will be decision region for this point that is, there will be an area of the signal space; in the signal space in which if the received vector lies, then we will detect this point.

So, if we transmit that point and we the received point is not in that decision region of this point then, there will be an error. So, suppose that the signal set is such that, the point has the decision region of this type; half plane on the left hand side of this line, this is the decision boundary for this point. This is our point and this is the decision boundary that is, if the received point is on this side of this line then, we detect this point otherwise, we detect some other point.

Then, what will be the probability of error for this point? So, we are transmitting this point and we have do find out, what is the probability that the received point will be on the right hand side of this line. So, note that the received point depends, only on the noise component in this direction. This is 2 dimensional plane and there are 2 components of the noise n_1 and n_2 . The n_2 does not matter; if we transmit this point, whatever is the value of n_2 it will still lie on in this decision region.

So, whether it is in the decision region of this point or not, will be determined by the value of n_1 alone. And for the received point to be in the decision region; this decision region, n_1 should be less than this value. So, suppose this distance is l ; l is the distance of this point from the decision boundary then, what is the probability of error? The probability of error is, the probability that n_1 is greater than l .

If, n_1 is greater than l the received point will be on the right hand side of this line. And what is this? This is nothing, but Q of l by σ that is, Q of $\frac{l}{\sigma}$ times l . Now, let us consider another type of decision region; another type of decision region is this; this is a strip. So, on either side suppose there is, this distance is l_1 and this distance; distance of the point from the decision boundary on the left is l_2 . Then, what is the probability of error? The probability of error all again, the error probability error depends on the value of N_1 alone, N_2 does not matter.

So, this probability is nothing, but the probability of error, is the probability that n_1 is greater than l_1 or n_1 is less than minus l_2 . In other words the probability of correct decision, we denote it by this notation; probability of correct decision is the probability that, n_1 is in this range. If the noise is in this range then, the decision will be correct because, the point received point will be in this region. And what is this? This is the area under the Gaussian PDF of unit variance; the sum of these areas. This is the probability that, n_1 will be greater than l_1 and this is the probability that, n_1 will be less than minus l_2 . Of course these points need to be computed because, there will be normalization.

This is the Q function is so that, this is the area of the Gaussian PDF with unit variance whereas, the noise may not have unit variance to start with. So, we need to normalize the, this point. We have seen these details in the last class. So, this will be l_1 by σ and this will be minus l_2 by σ . So, note that this area is Q of $\frac{l_1}{\sigma}$ and this area is Q of $\frac{l_2}{\sigma}$. This is minus, but, this area is same as, on this side, if we take this point on this side and take Q function the same it is symmetry; Gaussian PDF is symmetric.

So, these 2 areas together is Q of $\frac{l_1}{\sigma}$ plus Q of $\frac{l_2}{\sigma}$. This is the probability of error. So, this central of this area is 1 minus that. So, probability of error is Q of $\frac{l_1}{\sigma}$ plus Q of $\frac{l_2}{\sigma}$. Similarly, we can compute probability of error

for decision regions of other some other types, which we will do in a moment. Let us now consider the decision region of this type. Now, it is not only no 1 along 1 dimension, but let us say we have a decision region of this type.

(Refer Slide Time: 13:30)

$$\begin{aligned}
 P[C] &= P_r[n_1 < l_1 \text{ and } n_2 < l_2] \\
 &= P_r[n_1 < l_1] P_r[n_2 < l_2] \\
 &= \left(1 - Q\left(\frac{l_1}{\sigma}\right)\right) \left(1 - Q\left(\frac{l_2}{\sigma}\right)\right) \\
 P_e &= 1 - P[C] \\
 &= 1 - \left(1 - Q\left(\frac{l_1}{\sigma}\right)\right) \left(1 - Q\left(\frac{l_2}{\sigma}\right)\right) \\
 &= Q\left(\frac{l_1}{\sigma}\right) + Q\left(\frac{l_2}{\sigma}\right) - Q\left(\frac{l_1}{\sigma}\right) Q\left(\frac{l_2}{\sigma}\right)
 \end{aligned}$$

So, this is our point and suppose, this distance is l_1 and this distance is l_2 . Then what is the probability of correct for decision for this point? Probability of correct this point is the probability that, N_1 the noise component in this direction is less than l_1 this value, then it will be on this side of the line. So, n_1 should be less l_1 and the noise component in this direction, should be less than l_2 . So, n_2 should be less than l_2 .

Since, n_1 have and n_2 are independent of each other, this can be written as fact factor of the 2 probabilities. So, probability of n_1 less than l_1 times probability of n_2 less than l_2 . And what is this probability? This probability is nothing, but 1 minus the probability that n is greater than l_1 and that is, Q of l_1 by σ . And this is similarly 1 minus Q of l_2 by σ .

So, the probability of correct decision is expressed in terms of l_1 , l_2 and σ this way. Now, from here we can compute the probability of error that is, 1 minus probability of the correct decision that is, 1 minus these 2 factors times 1 minus Q of l_2 by σ . This can be of course, simplified and this product, from the product 1 will cancel and then, we will have Q of l_1 by σ plus Q of l_2 by σ times minus Q of l_1 by σ times Q of l_2 by σ .

Now, let us consider another type of decision region. So, these are all similar in nature and can be computed in similar manner. So, this type of decision region.

(Refer Slide Time: 16:28)

So, this is the decision region and let us not, considers any arbitrary distance here, here and here of course, that also can be computed simply, but we will let us just simply assume that all these distances are same. If they are not same, the expression will be little more complicated, but the method is as simple as this case; just like the previous 3 examples.

So let us suppose that, all these distances are 1 that is, this is distance 1 away from all these lines; this line, this line and this line. Then, what is the probability of error? Probability of error is 1 minus probability of the correct decision and what is probability of correct decision for this? This is the probability that, n_1 is less than this 1 and n_2 . So, and we can now factorize because, n_1 and n_2 are independent of each other and probability that n_2 is, n_2 is in this range minus 1 to 1. Then, it will be in this range. So, this is the probability of correct decision. And what is this; probability of n_1 less than 1 is 1 minus probability of n_1 greater than 1 and that is, 1 minus Q of 1 by sigma. And then this is, remember we have already computed probability of this type in 1 of the slides. This is basically the area of this type; probability of n_2 being in this range. So, this is 1 minus the 1 minus 2 times this area. So, 1 minus 2 times Q of, this is 1 by sigma then 2 times this area that is, 2 times Q of 1 by sigma.

So, this is the probability of correct decision. So, probability of error is $1 - (1 - 2Q(1/\sigma))^2$. And we can expand the product and simplify the expression. Similarly, we can similarly and finally, we let us compute the probability of error, for a point with this type of decision region.

(Refer Slide Time: 19:31)

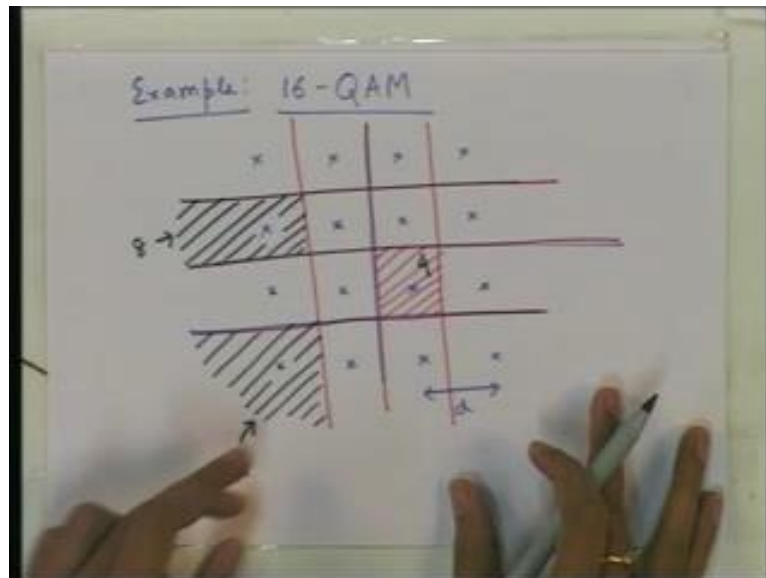

The point is at the centre and this distance is 1 from all sides; 1 this is 1 from all sides. Then what is the probability of correct decision? It is probability that, n_1 is in this range and also n_2 is in this range. And we know that n_1 and n_2 are independent, but identically distributed, both are Gaussian with same variance. So, these 2 are same. So, this is, 1 of this square and what is this probability? This is the again the area here; this area and that is $1 - 2$ times this area. So, this is $1 - 2$ times Q of 1 by σ and Whole Square.

So, probability of error for this type of decision region is, $1 - (1 - 2Q(1/\sigma))^2$. So, we have seen for different type of decision region, what will be the probability of error. Now, in a particular signal constellation different points will have different shape of decision region. And there are some, there is a whole family of signal sets, for which the points have decision regions of these types, that we have just now considered. Either it is a box or it is 1 side open, but 1 side closed or all these types that we have considered.

So, there is a whole family of signal sets for which the decision regions of different points are of these types. So, for those signal sets, we will be able to use this probability of error calculation techniques to compute the average probability of error for the signal set. Let us take 1 example and try to compute the probability of error for that signal set. So, let us take 16 QAM constellation for example.

(Refer Slide Time: 22:07)

So, we have a 16 QAM constellation and suppose that, this distance is d . And we know that, this d actually related to the average energy of this signal set. If we know d , we can compute the average energy of the signal set and vice-versa. So, let us just take d as the parameter and compute the probability of error in terms of d and the noise variance σ^2 .

So, let us try to find out first what of the types of decision regions that these points have? So, decision regions are like this; these are the decision boundaries and this is also there. So, let us plot; let us draw with red ink. So, this is 1 decision 1 boundary, this is another decision boundary, this is a decision boundary then, this is a decision boundary, this is a decision boundary and this is also a decision boundary. So, what are types of what are shapes of decision regions we have got?

We have got, 1 this close rectangular decision region. We have 4 such points, for which decision region has this shape, this point, this point, this point and this point and then, we have decision region of; say this type and there are 4 such points for which the decision

region has this shape this 1, this 1, this 1 and this 1. The orientation of this shape does not matter for the probability of error because, it is just rotation or we know that, rotation of decision region does not change the probability of error rotation or translation.

So and there is another type of decision region in this and that is, like this and there are 8 such points for which, the decision region has this shape; this point, this point, this point, this point, this, this, this and this. So, there are 8 such points. So, this decision this type of decision region is there for 8 points, this type of decision region is there for 4 times and this type decision region is there for 4 times.

Now, let us; so this is important because, we would like to compute the average probability of error. Now average has to be taken over all the 16 points. So, we will compute the probability of error for this point that is if, this point is transmitted, what is the probability that, there will be an error in detection. We will compute that and we will assume that, that is the probability of error for each of these 4 points. And then; we will compute the probability of error for this point, we will compute probability of error for this point and then this probability of error will be the same for all these points and this will be same for all these points.

So, let us compute the probability of error for 3 of those points. First let us take this point and we have already computed, we have seen how to compute if this distance in this case is $d/2$ because, this is the d and this is $d/2$. So, l equal to $d/2$. We have already computed this probability of error for such decision region and for we have do just put l equal to $d/2$ here.

(Refer Slide Time: 27:00)

The image shows a whiteboard with the following handwritten equations:

$$P_{e1} = 1 - \left(1 - 2Q\left(\frac{d}{2\sigma}\right)\right)^2 \quad - 4 \text{ Points}$$

$$P_{e2} = 1 - \left(1 - Q\left(\frac{d}{2\sigma}\right)\right)^2 \quad - 4 \text{ Points}$$

$$P_{e3} = 1 - \left(1 - Q\left(\frac{d}{2\sigma}\right)\right) \left(1 - 2Q\left(\frac{d}{2\sigma}\right)\right) \quad - 8 \text{ Points}$$

$$P_e = \frac{4}{16} P_{e1} + \frac{4}{16} P_{e3} + \frac{8}{16} P_{e2}$$

$$= \frac{1}{4} \left[1 - \left(1 - 4Q\left(\frac{d}{2\sigma}\right) + 4\left(Q\left(\frac{d}{2\sigma}\right)\right)^2\right) \right]$$

$$+ \frac{1}{2} \left[1 - \left(1 - 3Q\left(\frac{d}{2\sigma}\right) + 2\left(Q\left(\frac{d}{2\sigma}\right)\right)^2\right) \right]$$

$$+ \frac{1}{4} \left[1 - \left(1 - 2Q\left(\frac{d}{2\sigma}\right) + \left(Q\left(\frac{d}{2\sigma}\right)\right)^2\right) \right]$$

We will just copy this and so we have here; let us denote this probability of error by P_{e1} . This is $1 - (1 - 2Q(d/2\sigma))^2$. So, now let us take another point; let us take this point and find the probability of error. And this distance is also $d/2$, this distance is also $d/2$. So, we have also computed the probability of error for this type decision region and that is; here.

The probability of error is; let us denoted by P_{e2} . This is $1 - (1 - Q(d/2\sigma))^2$. So, $1 - (1 - Q(d/2\sigma))^2$. So, $d/2$ and both l_1 and l_2 in this case is $d/2$. So, $d/2\sigma$ times $1 - Q$, again the same quantity. So, we will have square of this. And there is another type decision region that is, now this is left. So, for this also we have computed the probability of error before and that is; this.

So, let us denote it by P_{e3} . So, this P_{e3} is $1 - (1 - Q(d/2\sigma))(1 - 2Q(d/2\sigma))$. So, we have computed the probability of error for these 3 types of decision regions that come in this 16 QAM constellation. Now this P_{e1} ; this probability this same probability of error is valid for these 4 points. So, there are 4 points for which, this is the probability of error and there are; this P_{e2} is for this point and there are 4 such points also.

So, there are 4 points for which, this is the probability of error and there are 8 points for which, this is the probability of error. So, what will be the average of the average probability of error of the 16 QAM constellation? We have to take 4 times this plus 4

times this plus 8 times this by 16. So; that means, 4 by 16 times this plus 4 by 16 time this plus 8 by 16 this. So, average probability of error P_e is: 4 by 16 times P_{e1} plus 8 by 16 times P_{e3} plus 4 by 16 times P_{e2} .

So, let us write this down; this is the one-fourth times 1 minus let us take the whole square. Let us expand the square; this will be 1 minus 4 times $Q d$ by 2 sigma plus 4 times $Q d$ by 2 sigma whole square. Then, plus half P_{e3} this let us expand this product also; we have 1 minus 3 times Q of d by 2 sigma plus 2 times $Q d$ by 2 sigma square plus one-fourth times P_{e2} that is, 1 minus let us again expand this square we get, 1 minus 2 $Q d$ by 2 sigma and plus $Q d$ by 2 sigma square.

(Refer Slide Time: 32:20)

$$\begin{aligned}
 P_e &= \frac{4}{16} P_{e1} + \frac{8}{16} P_{e3} + \frac{4}{16} P_{e2} \\
 &= \frac{1}{4} \left[1 - 4Q\left(\frac{d}{2\sigma}\right) + 4\left(Q\left(\frac{d}{2\sigma}\right)\right)^2 \right] \\
 &\quad + \frac{1}{2} \left[1 - 3Q\left(\frac{d}{2\sigma}\right) + 2\left(Q\left(\frac{d}{2\sigma}\right)\right)^2 \right] \\
 &\quad + \frac{1}{4} \left[1 - 2Q\left(\frac{d}{2\sigma}\right) + \left(Q\left(\frac{d}{2\sigma}\right)\right)^2 \right] \\
 &= Q\left(\frac{d}{2\sigma}\right) + \frac{3}{2}Q\left(\frac{d}{2\sigma}\right) + \frac{1}{2}Q\left(\frac{d}{2\sigma}\right) \\
 &\quad - \left[Q\left(\frac{d}{2\sigma}\right)^2 + Q\left(\frac{d}{2\sigma}\right)^2 + \frac{1}{4}Q\left(\frac{d}{2\sigma}\right)^2 \right] \\
 &= 3Q\left(\frac{d}{2\sigma}\right) - 2.25\left(Q\left(\frac{d}{2\sigma}\right)\right)^2
 \end{aligned}$$

So, this can be simplified; this 1 all, this 1 cancels with this 1, this 1 cancels with this 1 cancels with this 1. So, what we have now is; this minus goes inside and this signs change. So this is plus, this is plus, this is plus and these signs are minus. So, let us add all these terms and we get after multiplying by these factors; so one-fourth times 4. So, this is $Q d$ by 2 sigma plus half times 3. So, that is 3 by 2 $Q d$ by 2 sigma. Then, one-fourth times 2 that is, half $Q d$ by sigma and minus all these terms multiplied by the corresponding factors.

So, this is the one-fourth times 4 that is $Q d$ by 2 sigma whole square then half times 2 that is, again $Q d$ by 2 sigma whole square, it is one-fourth d by 2 sigma whole square. The square is on the whole Q function. So we get: this is 3 by 2 plus half is 2 to 2 plus 1

is 3. So, $3 Q d \text{ by } 2 \text{ sigma minus}$, this is $2.25 Q d \text{ by } 2 \text{ sigma whole square}$. So, this is the probability; average probability of error of 16 QAM constellation and this is in terms of d and σ . And d can be expressed in terms of the average energy if wanted.

For example, let us just see; what will be the average energy of the signal set in terms of d . We have the signal set like this. Now, what is the...? This is the origin. So, what is the energy of this point? This point has energy; this $d \text{ by } 2$. So, $d \text{ by } 2 \text{ whole square plus } d \text{ by } 2 \text{ whole square}$, this is also $d \text{ by } 2$. So, $2 \text{ times } d \text{ by } 2 \text{ whole square}$ that is, $d \text{ square by } 2$. So, the average energy E_s is; there are 4 such points.

(Refer Slide Time: 35:22)

$$\begin{aligned}
 &= Q\left(\frac{d}{2\sigma}\right) + \frac{3}{2}Q\left(\frac{d}{2\sigma}\right) + \frac{1}{2}Q\left(\frac{d}{2\sigma}\right) \\
 &\quad - \left[Q\left(\frac{d}{2\sigma}\right)^2 + Q\left(\frac{d}{2\sigma}\right)^2 + \frac{1}{4}Q\left(\frac{d}{2\sigma}\right)^2 \right] \\
 &= 3Q\left(\frac{d}{2\sigma}\right) - 2.25\left(Q\left(\frac{d}{2\sigma}\right)\right)^2 \\
 E_s &= \frac{4}{16} \cdot 2\left(\frac{d}{2}\right)^2 + \frac{8}{16} \left[\left(\frac{3d}{2}\right)^2 + \left(\frac{d}{2}\right)^2 \right] \\
 &\quad + \frac{4}{16} \cdot 2\left(\frac{3d}{2}\right)^2 \\
 &= \frac{1}{4} \left[\frac{d^2}{2} + 5d^2 + \frac{9d^2}{2} \right] \\
 &= 2.5d^2 = \frac{5}{2}d^2 \\
 \Rightarrow d &= \sqrt{\frac{2E_s}{5}} \quad P_e = 3Q\left(\sqrt{\frac{E_s}{5P_{avg}}}\right) - 2.25\left(Q\left(\sqrt{\frac{E_s}{5P_{avg}}}\right)\right)^2
 \end{aligned}$$

So, $4 \text{ by } 16 \text{ times } 2 \text{ times } d \text{ by } 2 \text{ whole square}$; $2 \text{ times } d \text{ by } 2 \text{ whole square}$ is the energy of that point and there are 4 such points so, $4 \text{ by } 16$. Total number of points is 16. So, you are averaging the energy of all the points. Then, there are 8 points of same energy of this type; this this this this this this this this this.

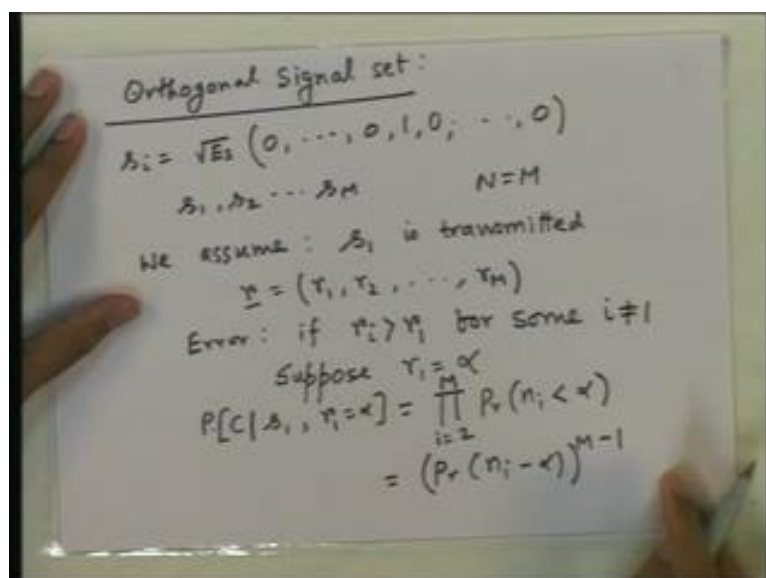

So, energy of this point is $3d \text{ by } 2$, this distance is $3d \text{ by } 2 \text{ whole square plus } d \text{ by } 2 \text{ whole square}$. This is the energy of this point and that is there 8 times. So, $8 \text{ by } 16 \text{ times } 3d \text{ by } 2 \text{ whole square plus } d \text{ by } 2 \text{ whole square plus again}$; there are 4 points of this type and energy of this is; $3d \text{ by } 2 \text{ whole square plus } 3d \text{ by } 2 \text{ whole square}$ that is, $2 \text{ times } 3d \text{ by } 2 \text{ whole square}$. And this becomes one-fourth $d \text{ square by } 2 \text{ plus } 5d \text{ square plus } 9d \text{ square by } 2$. that is, we get $9d \text{ square by } 2 \text{ plus } d \text{ square by } 2 \text{ is } 10d \text{ square by } 2$ that is,

$5d^2$ plus $5d^2$ plus $5d^2$ plus $10d^2$ plus $10d^2$ by 4. That is, $2.5d^2$.

So, that means, d is, this is $5 \times 2d^2$, d is $\sqrt{2E_s/5}$. So, this d by 2σ term; now the σ is $\sqrt{N/2}$. So, this term becomes; so, the probability of error becomes $3Q(\sqrt{2E_s/5N})$ then the same quantity whole square Q same thing, then square. So, this is instead of expressing the probability of error in terms of d , we expressed in terms of the average energy of the signal set so that, we know as we change the average energy of transmitted energy; how the probability of error changes. And it will be good exercise for you to actually verify this by simulation.

Take a 16 QAM constellation, add white Gaussian noise in the channel and do usual deduction and find out what probability of error you get by simulating, by transmitting the large number of symbols. And then, compare it with this value; this value can be computed in terms of the Erfc function that is available in mat lab. So, I can verify this by simulation. Let us now, try to see how to compute probability of error for other types of signals sets. For QAM type of signal sets this is very simple because, we have the decision regions of those shapes. Now, let us take some other modulation techniques and find out how to compute the probability of error. We next consider orthogonal signal sets.

(Refer Slide Time: 39:52)

So, what is the set of transmitted points? It is $\sqrt{E_s}$ times the i th transmitted point is all zeros except for the i th component 1 and then that is multiplied by $\sqrt{E_s}$. If you multiply this the energy of this becomes E_s . So, this is the i th transmitted point and there are M such points s_1 to s_M there are M components here. The dimension is same as M . So, N is the dimension is same as M . And suppose we received the every component is added by some noise and we received some vector or r .

So since, the signal set is actually symmetric, the probability of error for all each point is same. So, we need to compute only the probability of error for 1 particular point and that will be the probability of error for all the points and as a result it will also be same as the average probability of error.

So, we assume that s_1 is transmitted then, try to find out what is the probability of error. Now, what is the detection scheme? We know that for orthogonal signal set the optimum detection the ml detection simplifies to the following: that take the components of the received vector r_1, r_2, r_M . Choose the largest; choose the largest component and the index of that is the message transmitted that is, index that was transmitted. So, if r_i is the maximum out of this then, s_i was transmitted.

So, if we now assume that we transmitted s_1 and try to find out what is the probability of error; the error will happen if there is some other component here, which is greater than r_1 . So, there will be error if, r_i is greater than r_1 for some i not equal to 1. So, let us assume that in this component we have received; suppose, r_1 is equal to α ; some value α , suppose we have received r_1 equal to α then, what is the probability of error? The probability of error that is, the probability of; we will first compute the probability of correct detection and then compute probability of error.

So, probability of correct deduction given that: we transmitted s_1 and we received r_1 equal to α . Then what is this probability? That correct decision will be made if, each r_i is less than equal to r_1 for every i not equal to 1. Now there are, $M - 1$ such value of i . For each of them r_i must be less than r_1 . So, what is the probability that r_i is less than r_1 ? Remember that, at the i th component we transmitted 0 because, we transmitted the vector s_1 . So, the i th component we transmitted 0. So, r_i is basically the noise component n_i .

So, the probability that r_i is less than α , is same as the probability that n_i is less than α because, r_i is equal to n_i for i not equal to 1. And this is for i equal to 2 to n . So, n_i are independent of each other. So, we can take the product. So, this is and this will be same for because, this is all $n_i(s)$ have the same distribution. So, we have probability n_i minus α power M minus 1.

The image shows a whiteboard with handwritten mathematical derivations. On the left, there are two Gaussian distribution curves. The top curve is centered at α and has the area to its left shaded, labeled $Q\left(\frac{\alpha}{\sqrt{\frac{N_0}{2}}}\right)$. The bottom curve is centered at α and has the area to its right shaded, labeled $1 - Q\left(\frac{\alpha}{\sqrt{\frac{N_0}{2}}}\right)$. The main derivation is as follows:

$$P[C] = P[C|s_1] = \int_{-\infty}^{\alpha} p_n(x - \sqrt{E_s}) \left(\int_{-\infty}^x p_n(x) dx \right)^{M-1} dx$$

$$= \int_{-\infty}^{\alpha} p_n(x - \sqrt{E_s}) \left(Q\left(\frac{-x}{\sqrt{\frac{N_0}{2}}}\right) \right)^{M-1} dx$$

$$+ \int_{\alpha}^{\infty} p_n(x - \sqrt{E_s}) \left(1 - Q\left(\frac{x}{\sqrt{\frac{N_0}{2}}}\right) \right)^{M-1} dx$$

Below the equations, it is written that $P_e = 1 - P[C]$.

And this can be written in terms of the density function of the noise; all the n_i have the same density function and we denote it by this have, density function P_n . Then, this can be written as minus infinity to infinity $P_n \times dx$ whole power M minus 1. So, this is less than α , minus infinity to α . So, n_i ; value of n_i is taken from minus infinity to α . So, what is the probability that n_i is in this range? So, that is the obtained by integrating the density function in this range.

Now, this α itself may be of different value. So, to take the average probability of error given that; s_1 is transmitted that is, to compute probability of correct detection, given s_1 is transmitted. We have to now integrate average over all values of α also that is; we have to take value of α from minus infinity to infinity then, take the density of n_1 being such that r_1 is equal to α . Now, when will r_1 be equal to α ? At the first component we transmitted root over E_s , we transmitted in the first component toward E_s because, s_1 is transmitted, in the first component of the s_1 is root over E_s and we receive α as the first component. Then, n_1 must be α minus root over E_s .

So, n_1 is α minus root over ϵ_s and the density at that point is αP_n of α minus root over ϵ_s . So, this is the value of the density at α minus root over ϵ_s . And this time now we have to take this quantity. So, if α is received that the first component what, this is the probability that there will be error. So, we have to multiply by this minus infinity to α and $P_n \times dx$ or $M - 1 d\alpha$. And this can be now written in to, this can be written in to 2 parts 2 cases; for α minus infinity is 0 and for α 0 to infinity because if, α is positive this value has a is defined to be the Q function 1 minus Q function.

So, let us just see; if α is negative, what is this integral? If α is negative then, this integral is nothing, but take this density function and then minus infinity to α . So, this is nothing, but Q of minus α ; minus α is positive Q of minus α by, you have to divide by the standard duration of the noise that is, root over N naught by 2. This is; this integral when α is negative. When α is positive, what is this area? This is the 1 minus Q of this. So, this is 1 minus Q α by root over N naught by 2.

So, here we have for α negative; minus infinity to infinity a minus infinity to 0, we have $P_n \alpha$ minus root over ϵ_s times this quantity is now, Q of minus α by root over N naught by 2 this power $m - 1 d\alpha$ plus for α positive, we have $P_n \alpha$ minus root over ϵ_s times 1 minus Q α by root over N naught by to whole power $M - 1 d\alpha$.

So, we have this is actually good enough, but we have written it in terms of our known Q function. But, this does not actually allow us to compute this integration still because, this Q function does not have a closed form expression. We can compute it numerically and there are also tables for the values. So, only way to compute this will be, by numerical integration. And once we get this we know that, probability of error is 1 minus probability of correct decision. And probability of correct decision is same as this for s_1 because, it is same all symbols. So, this is 1 minus this. So, this itself is P C and then we get the probability of error this way.

So, this needs to be computed in numerical fashion because, this expression is not really very nice; is quite complicated. By it can be computed quite efficiently using mat lab, by numerical integration. So, in this class we have seen how to compute the probability of

error for some rectangular decision region shapes and then used that kind of computation technique to find the probability of error of 16 QAM constellation. And it can be used the same technique to compute any QAM constellation, the probability of error for any QAM constellation. And then, we have also seen how to compute probability of error for orthogonal signal set like, fsk ppm.

And in the next class, we will continue and see some more techniques and also will see when the exact probability of error is difficult to compute; whether we can get a bound which is much easier to compute or expressed in a much simpler way.

Thank you. See you in the next class.
