**BER with Diversity**

(Refer Slide Time: 00:38)

Welcome to another lecture of the course in 3G and 4G, wireless mobile communication systems. In the last lecture, we started our analysis of wireless communication systems with diversity, we said we can have a system in which instead of one transmit, one receive antenna we can have L receive antennas. The signals at the L receive antenna received at the L receive antennas can be represented as  $y_1, y_2$  so on, up to  $y_n$ . And at the receiver, we can combine those received signals with weights  $w_1, w_2, w_1$  as  $w_1$  conjugate  $y_1, w_2$  conjugate  $y_2$  so on up to  $w_L$  conjugate  $y_L$ .

(Refer Slide Time: 00:56)

The whiteboard shows the following derivation:

$$\bar{w}^H \bar{y}$$
$$\bar{y} = \bar{h}x + \bar{n}$$

Beamformer output

$$= \bar{w}^H (\bar{h}x + \bar{n})$$
$$= \underbrace{\bar{w}^H \bar{h}x}_{\text{signal component}} + \underbrace{\bar{w}^H \bar{n}}_{\text{noise component}}$$

We also said that this can be succinctly represented in vector notation as  $\bar{w}^H \bar{y}$ , this linear combination of the signals  $L$  signals received across, the  $L$  receive antennas can be represented using vector notation as  $\bar{w}^H \bar{h}$ ,  $\bar{y}$ .

(Refer Slide Time: 01:30)

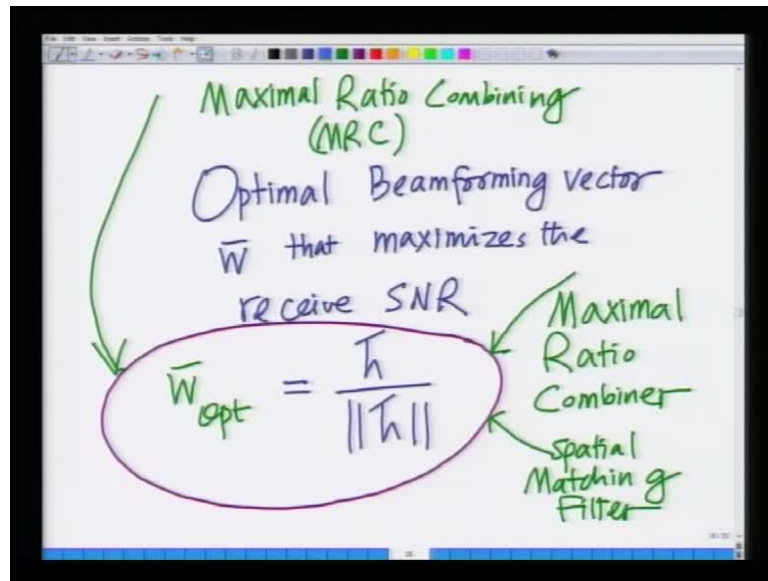

The whiteboard shows the following derivation:

$$\text{Max } \underbrace{|\bar{w}^H \bar{h}|^2}_{\text{signal component}} \frac{P}{\sigma_n^2}$$
$$\bar{w} = c \bar{h}$$
$$c^* \|\bar{h}\|^2 = 1$$
$$c = \frac{1}{\|\bar{h}\|^2}$$
$$\bar{a}^H \bar{b} = |\bar{a}| |\bar{b}| \cos \theta$$

$\theta = 0$

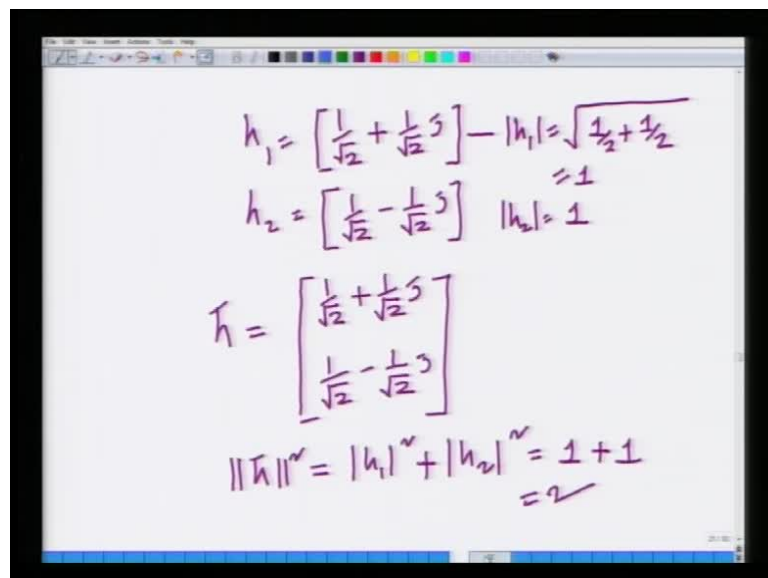

And we said we also wanted to derive that or compute that optimal vector  $\bar{w}$ , which maximizes the SNR at the receiver and we said that can be derived by maximizing  $\bar{w}^H \bar{h}$  norm square that is the vector  $\bar{w}$ , which maximizes  $\bar{w}^H \bar{h}$  norm square maximizes, the SNR at the receiver.

(Refer Slide Time: 01:44)

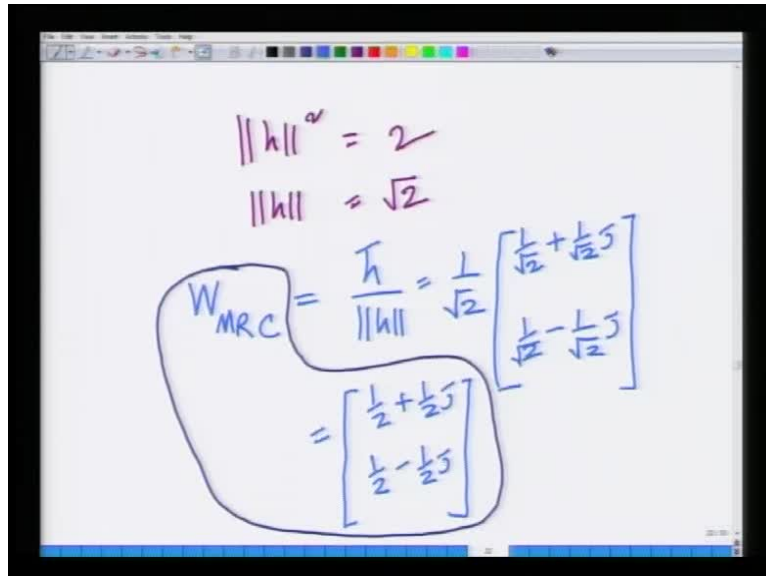

We derived an expression for that  $\bar{w}$  and we said that that  $\bar{w}$  optimal is  $\bar{h}$ , where  $\bar{h}$  is the vector of channel coefficients divided by norm  $\bar{h}$ . Hence, it is aligned with the channel vector essentially, the optimal SNR maximizing vector is nothing but identically equal to the channel fade, fading channel coefficient vector scaled by norm  $\bar{h}$ . Hence, it is also known as a maximal ratio combiner since, it maximizes the SNR it is also the special matching filter since, it is matched to the response of my array of  $L$  antennas.

(Refer Slide Time: 02:26)

We also started with an example where we said, I have a system with two receive antennas. The fading coefficient across the first receive antenna is  $1/\sqrt{2} + 1/\sqrt{2}j$ , across the second receive antenna is  $1/\sqrt{2} - 1/\sqrt{2}j$ .

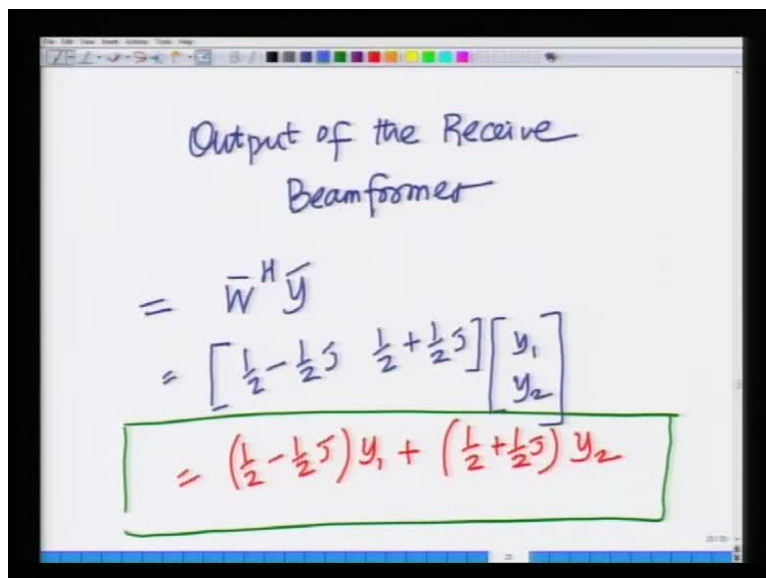

(Refer Slide Time: 02:38)

The image shows a handwritten derivation on a whiteboard. At the top, it states  $\|h\|^2 = 2$  and  $\|h\| = \sqrt{2}$ . Below this, the weight vector  $W_{MRC}$  is calculated as  $\frac{h}{\|h\|} = \frac{1}{\sqrt{2}} \begin{bmatrix} \frac{1}{\sqrt{2}} + \frac{1}{\sqrt{2}}j \\ \frac{1}{\sqrt{2}} - \frac{1}{\sqrt{2}}j \end{bmatrix}$ . This is then simplified to  $\begin{bmatrix} \frac{1}{2} + \frac{1}{2}j \\ \frac{1}{2} - \frac{1}{2}j \end{bmatrix}$ .

In this case, we derived the optimal maximal ratio combiner, and that we said is half plus half  $j$  and half minus half  $j$ .

(Refer Slide Time: 02:48)

The image shows a handwritten derivation on a whiteboard. It starts with the title "Output of the Receive Beamformer". Below this, it shows the calculation  $= \bar{W}^H \bar{y}$ , which is then expanded to  $= \begin{bmatrix} \frac{1}{2} - \frac{1}{2}j & \frac{1}{2} + \frac{1}{2}j \end{bmatrix} \begin{bmatrix} y_1 \\ y_2 \end{bmatrix}$ . The final result is boxed in green:  $= (\frac{1}{2} - \frac{1}{2}j)y_1 + (\frac{1}{2} + \frac{1}{2}j)y_2$ .

And we said the optimal combined statistics is given as  $w^H \bar{y}$ , which is half minus half  $j$  times  $y_1$  plus half plus half  $j$  times  $y_2$ , this is where we stopped last time, let me finish the discussion of this example.

(Refer Slide Time: 03:08)

The image shows a whiteboard with the following handwritten text and equations:

$$\|h\|^2 = 2$$

$$\|h\| = \sqrt{2}$$

Rx SNR after MRC

$$= \frac{\|h\|^2 P}{\sigma_n^2} = \frac{2P}{\sigma_n^2}$$

In this example particularly, we can see that norm  $h$  equals to for instance we saw here that norm  $h$  equals root 2 hence, norm  $h$  square norm  $h$  square equals to which means the received SNR after maximal ratio combining, received SNR after maximal ratio combining equals norm  $h$  square  $p$  over sigma  $n$  square, which in this case is 2  $p$  over sigma  $n$  square. Since, norm  $h$  were is 2 alright. So, for this case of the example with 2 receive antennas. We have derived the optimal maximal ratio combiner, we have derived the maximal ratio combining statistic at the output of the receiver, and we also have derived the SNR at the output of the maximal ratio combining receiver.

(Refer Slide Time: 04:34)

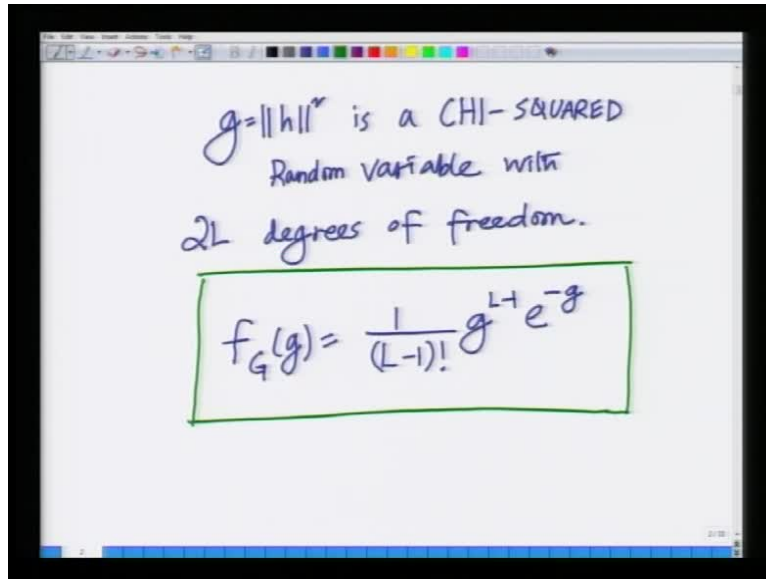

$$\begin{aligned} \text{Analysis of BER of} \\ \text{Multiple Antenna System} \\ R_x \text{ SNR} &= \|h\|^2 \frac{P}{\sigma_n^2} \\ &= (|h_1|^2 + |h_2|^2 + \dots + |h_L|^2) \frac{P}{\sigma_n^2} \\ &= g \frac{P}{\sigma_n^2} \\ g &= |h_1|^2 + |h_2|^2 + \dots + |h_L|^2 \end{aligned}$$

Now, let us move on to analysis of the complete analysis of the bit error rate performance of this maximal ratio combining, multiple receive antenna receiver. So, we will start our discussion today with an analysis. So, let me give the title of this that is an analysis of bit error rate of this, multiple antenna bit error rate analysis of the bit error rate of this multiple antenna system.

We have seen that the receive SNR, the receive SNR equals norm h square p over sigma n square where norm h square is the norm of the vector of channel coefficients, and this can be written as magnitude h 1 square plus magnitude h 2 square plus magnitude h 1 square p over sigma n square, that is the received SNR at the output of the maximal ratio of combiner is nothing but magnitude h 1 square plus magnitude h 2 square so on up to magnitude h 1 square times p over sigma n square.

Where each magnitude h i square is the square of the magnitude of the fading coefficient of the ith fading coefficient, which is the fading coefficient between transmit antenna and the ith receive antenna. And this can also be represented as g times p over sigma n squared where g is the overall gain of the channel is nothing but summation, magnitude h 1 square magnitude h 2 square so on up to magnitude h 1 square. So, I am representing this succinctly at the received SNR a received SNR as g, where g is the gain of this channel across the multiple receive antennas times p over sigma n square that is g is the gain of the channel, after the maximal ratio combining process at the receiver.

(Refer Slide Time: 06:49)

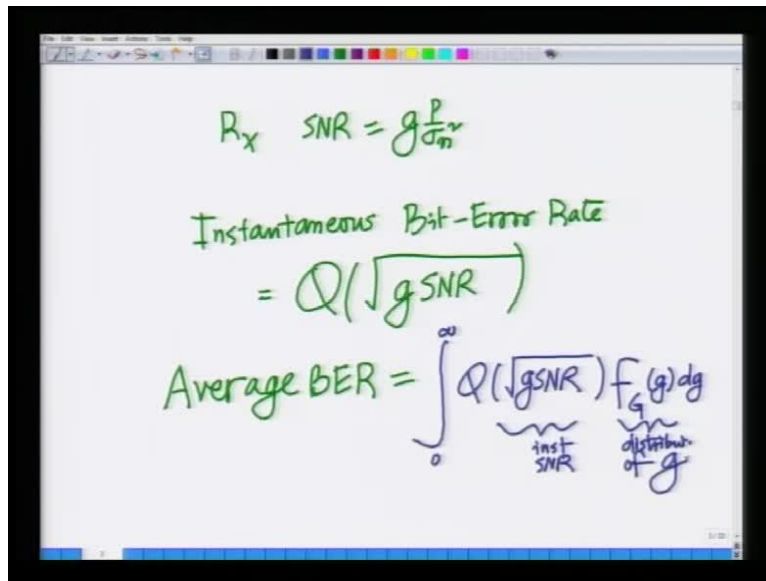

$g = \|h\|^2$  is a CHI-SQUARED  
Random variable with  
 $2L$  degrees of freedom.

$$f_g(g) = \frac{1}{(L-1)!} g^{L-1} e^{-g}$$

Now,  $g$  which is equal to norm  $h$  square is a well known random variable, with certain properties, its properties have been studied elaborately, in the literature on statistics and mathematics. It has been shown that  $g$  equal to norm  $h$  square is a chi squared, it is a chi squared random variable with  $2L$  degrees of freedom. It has been shown in literature, that when each of the fading coefficients is Rayleigh, magnitude is Rayleigh in nature that is each  $h_i$  has a fading coefficient, whose real part and imaginary part are Gaussian and also they are independent, uncorrelated or independent of each other.

Hence, when I combine the magnitude squares of  $L$  such quantities, the resulting gain  $g$  which is nothing but magnitude  $h_1$  square, magnitude  $h_2$  square so on up to magnitude  $h_L$  square is a chi squared random variable with  $2L$  degrees of freedom, where  $L$  is the number of receive antennas. And because of the time limitation of this course we would not go elaborately, or we would not go into detailed into the properties of this chi square random variable, but I will just write down the distribution of this chi square random variable over here.

(Refer Slide Time: 09:43)

$$R_x \text{ SNR} = g \frac{P}{\sigma_n^2}$$
$$\text{Instantaneous Bit-Error Rate} = Q(\sqrt{g \text{SNR}})$$
$$\text{Average BER} = \int_0^{\infty} Q(\sqrt{g \text{SNR}}) f_g(g) dg$$

inst SNR      in distribn of g

It can be shown that the distribution,  $f_g$  of this gain  $g$  of this chi square random variable of  $2L$  degrees of freedom is shown to be given as,  $1$  over  $L$  minus  $1$  factorial times  $g$  to the power of  $L$  minus  $1$ ,  $e$  to the power of minus  $g$ . So, in other words the distribution of this gain  $g$  is  $f_g$  of  $g$ , which is  $1$  over  $L$  minus  $1$  factorial times  $g$ ,  $g$  to the power of  $L$  minus  $1$  times  $e$  to the power of minus  $g$ .

Now, why is this essential for us, remember similar to the ray fading channel case, where we looked at the gain at the gain a square, we said that the instantaneous bit error rate is a function of  $a$  and then we average over, the distribution of  $a$  which is nothing but the ray fading distribution. Similarly, here we are going to look at the instantaneous SNR and average over the distribution of the gain to get the average SNR. And hence, we know that the received SNR, as we have just seen in the previous page received SNR is  $g$  times  $p$  over  $\sigma_n^2$  hence, the instantaneous bit error rate.

The instantaneous bit error rate is nothing but it is  $Q$  function, remember a instantaneous bit error rate is nothing but  $Q$  function of the square root of SNR hence, in this case the instantaneous bit error rate is nothing but  $Q$  times  $g$  of SNR, where SNR is  $p$  over  $\sigma_n^2$ . Now, to get the average bit error rate to get the average bit error rate from this instantaneous bit error rate, I have to average this  $Q$  of square root  $g$  SNR which is a function of  $g$  over the distribution of  $g$ .

So, the average is simply given as 0 to infinity  $q$  of square root of  $g$  over  $g$  SNR times  $f$  of  $g$  of  $g$   $d$   $g$  look at what I am doing over here, I am taking  $q$  square root of  $g$  SNR which is the instantaneous SNR, this is the instantaneous SNR and I am averaging it over the distribution of  $g$ , which is the distribution in the distribution is a chi squared distribution with  $2L$  degrees of freedom alright. So, this is the distribution of the gain  $g$ . Now, we will not go into the details of this derivation as we did in the case of a ray fading channel because this is slightly more complicated, than the previous case the previous simple case of  $L$  equals to 1 at receive antenna, which is the ray fading channel. So, we will simply I will simply write down the expression over here.

(Refer Slide Time: 12:01)

The image shows a handwritten derivation on a whiteboard. The title is "BER with L Receive antennas after MRC combining". The main equation is:

$$= \left(\frac{1-\lambda}{2}\right)^L \sum_{l=0}^{L-1} \binom{L+l-1}{l} \left(\frac{1+\lambda}{2}\right)^L$$

Below the main equation, there is a definition for  $\lambda$ :

$$\lambda \text{ is } \sqrt{\frac{\text{SNR}}{2 + \text{SNR}}}$$

To the left of the definition, there is a binomial coefficient formula:

$$\binom{n}{k} = \frac{n!}{k!(n-k)!}$$

The bit error rate with  $L$  receive antennas after MRC combining the bit error rate with  $L$  receive antennas after maximal ratio of combining, we derived the optimal maximal ratio combiner, in the last lecture is given as the expression is  $1 - \lambda$  over  $2$  to the power  $L$  times  $\sum_{l=0}^{L-1} \binom{L+l-1}{l} \left(\frac{1+\lambda}{2}\right)^L$  to the power  $L$ .

So, the complete expression for the bit error rate is given as  $1 - \lambda$  whole divide by  $2$  to the power of capital  $L$ , where capital  $L$  is the total number of receive antennas into summation  $l$  equals  $0$  to  $L - 1$ ,  $L$  plus small  $l$  the index minus  $1$ . Choose  $L$  remember  $n$  choose  $k$  or  $\binom{n}{k}$  is nothing but  $n$  factorial divided by  $k$  factorial times  $n - k$  factorial.

So, this is capital L plus small l minus 1 choose L or 1 plus 1 minus 1 c l into 1 plus lambda over 2 to the power l. Where lambda is defined as lambda is SNR divided by 2 plus SNR square root. So, we have a closed form expression for the bit error rate of a system, with n receive antennas after which employs maximal ratio combining that expression is given by this summation, where lambda is nothing but SNR divided by 2 plus SNR whole square root. And this is a slightly complicated expression.

(Refer Slide Time: 14:40)

The image shows a handwritten derivation on a whiteboard for the Bit Error Rate (BER) when the number of receive antennas \$L\$ is equal to 1. The steps are as follows:

$$L = 1$$

$$\left(\frac{1-\lambda}{2}\right) \sum_{l=0}^L \binom{L}{l} \left(\frac{1+\lambda}{2}\right)^l$$

$$= \left(\frac{1-\lambda}{2}\right) \cdot \binom{0}{0} \left(\frac{1+\lambda}{2}\right)^0$$

A green arrow points from the text "BER with Single Receive Antenna" to the binomial coefficient \$\binom{0}{0}\$, which is simplified to 1.

$$\text{BER} = \frac{1}{2}(1-\lambda) = \frac{1}{2}\left(1 - \sqrt{\frac{\text{SNR}}{2+\text{SNR}}}\right)$$

So, let me simplify this expression progressively first, let us start with the simple case that we know, let us start with the L equals one case l equals one case it is fairly simple it reduces to 1 minus lambda over 2 to the power of L, which is 1. So, it is simply 1 minus lambda over 2 into sigma l equals 0 to capital L minus 1, which is again 1 minus 1 which is 0 times capital L plus small l minus 1 capital L minus 1 is 0.

So, this is small l c l that is l choose l into 1 plus lambda over 2 to the power of l. Now, there is only one term in this expression, which is small l equals 0. So, this reduces to 1 minus lambda over 2 times 0 c 0 that is 0, choose 0 times 1 plus lambda over 2 to the power of 0, this whole term here is one which means this reduces to half 1 minus lambda equals half 1 minus SNR divided by 2 plus SNR square root.

We said for we said, we have an expression for any given number of receive antennas capital L specifically, for capital L equals 1, we derived the expression for bit error rate. So, bit error rate for l equals 1 equals half 1 minus SNR divided by 2 plus SNR square root and this is

nothing but if you recall this is nothing but we saw, this expression earlier this is the bit error rate in a ray fading wireless channel, with a single transmit antenna and single receive antenna this is bit error rate with single receive, this is the bit error rate of the wireless. Say communication system with a single receive antenna that is the same expression, as we see before. So, we are trying to say that it is consistent with what, we derived before in the case of a single receive antenna.

(Refer Slide Time: 17:22)

The image shows a whiteboard with the following handwritten text and equations:

For high SNR:

$$\begin{aligned} & \frac{1}{2}(1-\lambda) \\ &= \frac{1}{2}\left(1-\sqrt{\frac{\text{SNR}}{2+\text{SNR}}}\right) \\ &= \frac{1}{2}\left(1-\frac{1}{\left(1+\frac{2}{\text{SNR}}\right)^{1/2}}\right) \\ &= \frac{1}{2}\left(1-\left(1-\frac{1}{2}\frac{2}{\text{SNR}}\right)\right) \\ &= \frac{1}{2\text{SNR}} \end{aligned}$$

Now, let me slightly simplify this for the case of high SNR, let me simplify for so, let me write down here for high SNR. Now, for high SNR let us consider the term half into 1 minus lambda that is half into 1 minus SNR divided by 2 plus SNR square root, which can also be written as half into 1 minus 1 over 1 plus 2 over SNR to the power of half. So, look at this, this is half into 1 minus 1 over 1 plus 2 SNR to the power of half 1 plus 2 over SNR to the power of half is in the denominator.

Now, this as SNR increases this 2 over SNR term becomes progressively smaller which means, I can approximate this with a first order approximation and that approximation is nothing but 1 minus 1 plus 2 over SNR to the power of minus half is nothing but 1 minus half times 2 over SNR. So, this is 1 minus half times 2 over SNR and that is nothing but this one's cancel 1 minus 1. So, the net becomes one over 2 SNR. So, half 1 minus lambda for increasing SNR at high values of SNR is approximately equal to 1 over 2 SNR.

(Refer Slide Time: 19:17)

$$\begin{aligned}
 & \frac{1}{2}(1+\lambda) \\
 & \approx \frac{1}{2}\left(1+1-\frac{1}{\text{SNR}}\right) \\
 & = \frac{1}{2}\left(2-\frac{1}{\text{SNR}}\right) \\
 & \approx \frac{1}{2} \cdot 2 = 1
 \end{aligned}$$

At high SNR  $\left\{ \begin{array}{l} (1-\lambda)/2 \approx 1/2\text{SNR} \\ (1+\lambda)/2 \approx 1 \end{array} \right.$

Similarly, if I compute the approximation half of 1 plus lambda at high SNR this is approximately half 1. Now, instead of the minus inside I will have plus 1 minus 1 over SNR, this is equal to half 2 minus 1 over SNR as SNR increases 1 over SNR becomes smaller and smaller. Hence, it is small in comparison to 2 hence, this expression becomes half times 2 which is essentially 1. So, we said at high SNR 1 minus lambda over 2 approximately equal to 1 over 2 SNR and 1 plus lambda over 2 approximately equal 2, 1 that is at high SNR 1 minus lambda over 2 is approximately equal to 1 over 2 SNR and 1 plus lambda by 2 is approximately equal to 1. Now, substituting this back in the previous expression we had.

(Refer Slide Time: 20:54)

at high SNR

$$\begin{aligned}
 \text{Average BER} &= \left(\frac{1-\lambda}{2}\right)^L \sum_{l=0}^{L-1} \binom{L+l-1}{l} \left(\frac{1+\lambda}{2}\right)^l \\
 &= \left(\frac{1}{2\text{SNR}}\right)^L \sum_{l=0}^{L-1} \binom{L+l-1}{l} \\
 &= 2^{L-1} C_L \cdot \frac{1}{2^L} \cdot \left(\frac{1}{\text{SNR}}\right)^L
 \end{aligned}$$

We had average BER equals  $1 - \frac{\lambda}{2}$ , let me write down the complete expression here times  $\sum_{l=0}^{L-1} \binom{L-1}{l} \left(\frac{\lambda}{2}\right)^l \left(1 - \frac{\lambda}{2}\right)^{L-1-l}$ . Now,  $1 + \frac{\lambda}{2}$  is  $1$ ,  $1 - \frac{\lambda}{2}$  is nothing but  $\frac{1}{2} \text{SNR}$ . So, I can write this as  $\frac{1}{2} \text{SNR}$  to the power  $l$  into  $\sum_{l=0}^{L-1} \binom{L-1}{l} \left(\frac{1}{2}\right)^{L-1-l}$  or  $\frac{1}{2} \text{SNR}$  to the power of  $l$  into  $\frac{1}{2} \text{SNR}$  to the power of  $l$ .

So, this is simply reduces to the summation  $\sum_{l=0}^{L-1} \binom{L-1}{l} \left(\frac{1}{2}\right)^{L-1-l} \left(\frac{1}{2}\right)^l \text{SNR}^l$ . And hence this is  $2^{L-1} \sum_{l=0}^{L-1} \binom{L-1}{l} \left(\frac{1}{2}\right)^{L-1-l} \left(\frac{1}{2}\right)^l \text{SNR}^l$ . Hence, the final expression for the bit error rate at high SNR, let me write it here at high SNR. The final expression for bit error rate at high SNR is given as  $2^{L-1} \sum_{l=0}^{L-1} \binom{L-1}{l} \left(\frac{1}{2}\right)^{L-1-l} \left(\frac{1}{2}\right)^l \text{SNR}^l$  where  $l$  is nothing but the number of receive antennas.

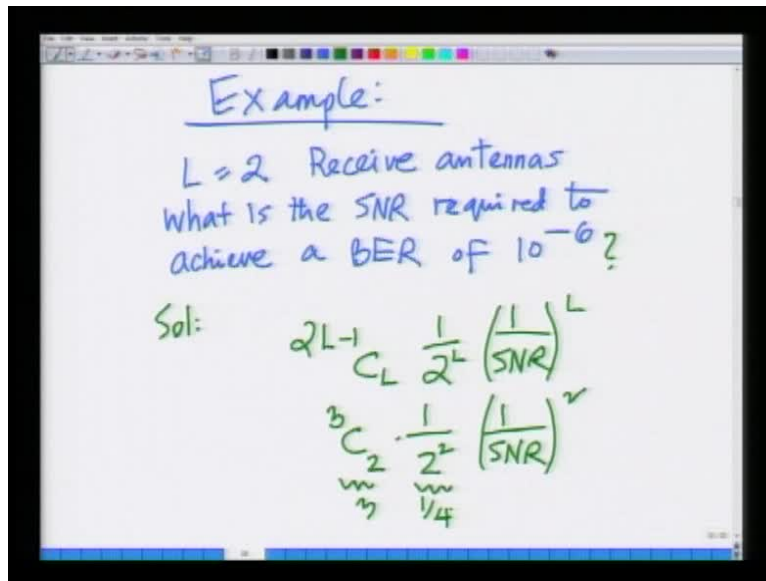

(Refer Slide Time: 23:02)

BER with  $L$  Rx Antennas  
after Maximal Ratio  
Combining @ high SNR

$$= 2^{L-1} \sum_{l=0}^{L-1} \binom{L-1}{l} \left(\frac{1}{2}\right)^L \text{SNR}^l$$

So, let me just rewrite that here clearly bit error rate with  $L$  receive antennas after maximal ratio combining at high SNR is equal to  $2^{L-1} \sum_{l=0}^{L-1} \binom{L-1}{l} \left(\frac{1}{2}\right)^L \text{SNR}^l$ , this is the expression for bit error rate with  $l$  receive antennas after maximal ratio combining and of course, you have to remember that it is a high SNR approximation this is not the exact expression, but this is a high SNR approximation. So, let us start with this expression and analyze it further first let us do an example to enhance our understanding.

(Refer Slide Time: 24:23)

So, let us do an example let us consider the previous case where  $L$  equals 2 receive antennas. I want to find out what is the bit error rate what is the SNR at which the bit error rate is  $10^{-6}$  remember in the AWGN case of the digital wired or wire line communication channel case, we did the similar example we found out the signal to noise power ratio at which, the bit error rate is  $10^{-6}$  is  $10^{-6}$ .

We did a similar example for a wireless communication system, with a single receive antenna and we found out that at bit error rate  $10^{-6}$ , the SNR required is very high in fact, it is 10,000 times higher than what is required in a wire line communication system. Now, we are trying to do similar a similar number computes similarly, the SNR required to achieve a bit error rate  $10^{-6}$  in a wireless communication system with  $L$  equals 2 receive antennas that is instead of a single receive antenna. I have  $L$  equals 2 that is to receive antennas.

Now, what is the SNR required is it lower is it higher, let us compute that to get an idea alright for  $L$  equals 2. What is let me write down the question, what is the SNR required to achieve a bit error rate of  $10^{-6}$ . What is the bit error rate required to achieve, what is the SNR required to achieve the bit error rate of  $10^{-6}$  in this wireless system with two receive antennas from previously, from what you have seen previously, the bit error rate at high SNR is  $2^{L-1} \binom{L-1}{L-1} \frac{1}{2^L} \left(\frac{1}{SNR}\right)^L$  to

the power of L. Now, L equals 2 so,  $2L - 1$  is 3 choose 2 or  $3C2$  times  $1/2^2$  times  $1/(\text{SNR})^2$ . 3 choose 2 is nothing but 3,  $1/2^2$  is nothing but  $1/4$ .

(Refer Slide Time: 27:09)

The image shows a whiteboard with the following handwritten equations in green and red ink:

$$\frac{3}{4} \left( \frac{1}{\text{SNR}} \right)^2 = 10^{-6}$$

$$\left( \frac{1}{\text{SNR}} \right)^2 = \frac{4}{3} \times 10^{-6}$$

$$\text{SNR}^2 = \frac{3}{4} \times 10^6$$

$$\text{SNR} = \sqrt{\frac{3}{4}} \times 10^3$$

Hence, this expression for bit error rate becomes  $3/4 \times 1/(\text{SNR})^2$  and I want this equal to that is the bit error rate equal to  $10^{-6}$ . So, I am saying the bit error as a function of SNR is  $3/4 \times 1/(\text{SNR})^2$  with L equals 2 receive antennas, I want a bit error rate equals  $10^{-6}$ . Hence, I am equating this to  $10^{-6}$  and now, so I can derive  $1/(\text{SNR})^2 = 4/3 \times 10^{-6}$  which means,  $\text{SNR}^2 = 3/4 \times 10^6$  which means,  $\text{SNR} = \sqrt{3/4} \times 10^3$ . I want to compute the SNR in dB.

(Refer Slide Time: 28:29)

The image shows a whiteboard with handwritten mathematical work. At the top, the equation  $SNR_{dB} = 10 \log_{10} \left( \frac{\sqrt{3}}{2} \times 10^3 \right)$  is written in red. Below it, the result  $= 29.37 \text{ dB}$  is also in red and circled in blue. In blue ink, the text reads "SNR req with only 1 antenna was 57 dB!". Below that, the calculation "Reduction is  $57 - 29 \text{ dB}$ " is written, followed by the result  $\approx 28 \text{ dB}$  which is also circled in blue.

The SNR in d b is  $10 \log_{10} \left( \frac{\sqrt{3}}{2} \times 10^3 \right)$ . This can be shown to be so, this SNR required in d b can be shown to be 29.37 d b. So, what I have been now computed, we have computed the SNR required to achieve a bit error of  $10^{-6}$  in a wireless communication system, with 2 receive antennas and we are saying that that SNR required is 29.37 d b. If you remember with one receive antenna, the SNR required, SNR required with only one antenna was if you remember, let me refresher your memory we computed. Similarly, the SNR required with one antenna we said that was 57 d b.

Now, when we added one more receive antenna to the system and we did some intelligent signal processing in terms of maximal ratio combining that SNR required has come down to approximately 29 d b. So, the reduction is 57 minus 29 d b approximately equal to 28 d b. So, because we have added an extra receive antenna in this wireless communication system, the amount of SNR required to achieve a bit error rate of  $10^{-6}$  has come down by 28 d b. Now, let me illustrate to you how significant this is.

(Refer Slide Time: 30:32)

$P_w^1$  = power reqd with  
1 Rx antenna

$P_w^2$  = power reqd with  
2 Rx antennas

$$10 \log_{10} \frac{P_w^1}{P_w^2} = 28 \approx 30 \text{ dB}$$
$$\frac{P_w^1}{P_w^2} = 10^3$$

So, let us say  $P_w^1$  equals power required with a single receive antenna  $P_w^2$  equals power required with 2 Rx antenna, then the power required with 2 Rx antennas is 28 dB or approximately 30 dB lower than the power required with 1 receive antenna. Hence, I can write  $10 \log_{10} \frac{P_w^1}{P_w^2}$  is equal to 28 dB, which is approximately 30 dB which means,  $\frac{P_w^1}{P_w^2}$  equals 10 to the power 3 which means,  $P_w^2$  equals  $P_w^1$  divided by 10 power 3 look at this  $P_w^2$  is the amount of power required with 2 receive antennas at the receiver  $P_w^1$  is the amount of power required with one receive antenna at the receiver, this is saying with 2 receive antennas  $P_w^2$  is  $P_w^1$  divided by 10 power 3 which is 1000.

(Refer Slide Time: 31:50)

The diagram shows the equation  $P_w^2 = P_w^1 / 10^3$ . A green arrow points from  $P_w^2$  to the text "Power with 2 Ant.". Another green arrow points from  $P_w^1$  to the text "Power with 1 antenna:". The text "10<sup>3</sup>" is written below the division line.

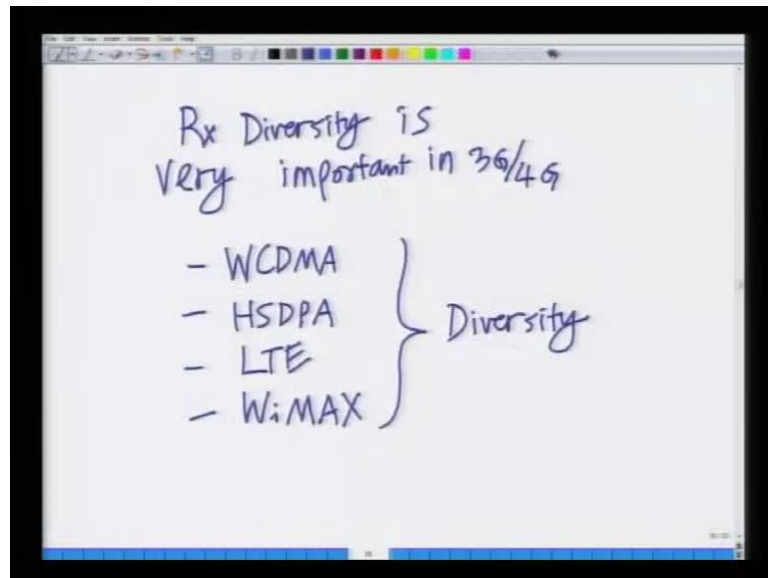

So, the amount of power required now is the thousand times lower compared to the case, when we had only a single receive antenna. So,  $P_w^2$  is power with two antennas and  $P_w^1$  is nothing but power with one antenna. Thus  $P_w^2$  is thousand times lesser than the power required with one antenna that is if 10 if a 10 kilo watt was required with one receive antenna. Now, we required 10 kilo watts by thousand which is simply 10 watts. So, added one more receive antenna has result in resultant in the significant improvement in the bit error rate at the receiver, let me summarize our conclusion.

(Refer Slide Time: 33:14)

Adding one more Rx antenna @ the wireless Receiver has significantly improved BER performance.

Adding one more R x antenna of the wireless system at the wireless receiver, has significantly improved bit error rate performance. So, adding one more receive antenna at the receiver in my wireless communication system, has significantly improved the bit error rate performance, and hence this scheme receive diversity is a very important technique in 3 G, 4 G wireless communication systems.

(Refer Slide Time: 34:12)

Hence, it is very R x diversity is very important in 3 G, 4 G, R x diversity is a key aspect of a receive antenna diversity is a key aspect, or diversity is a key aspect, in 3 G, 4 G wireless communication systems, it is employed in W C D M A, it is employed in H S D P A, it is employed in L T E. Remember in the first lecture, in the very first lecture we looked at a list of technologies that are basically, categorized or characterized as 3 G and 4 G technologies and we said several such technologies are W C D M A, H S D P A, L T E and wire max and all of these techniques used diversity.

Here we talked about receive diversity, but there is also a form of transmit diversity which we are going to talk about later. So, all these systems essentially use some form of diversity because diversity results in a significant decrease in the SNR, at the receiver hence, diversity is an key technology in 3 G, 4 G wireless communication systems. Hence, we will study this and this will be a critical component of all the technologies of the different technologies that we study in this course, which is essentially 3 G, 4 G wireless communications. So, let us see

why this decrease in bit error rate or why, this significant improvement inefficiency is arising in this system.

(Refer Slide Time: 36:04)

Why is BER decreasing with Rx Antennas?

for L antennas,

$$C_L \frac{1}{2^{L-1}} \left(\frac{1}{\text{SNR}}\right)^L$$

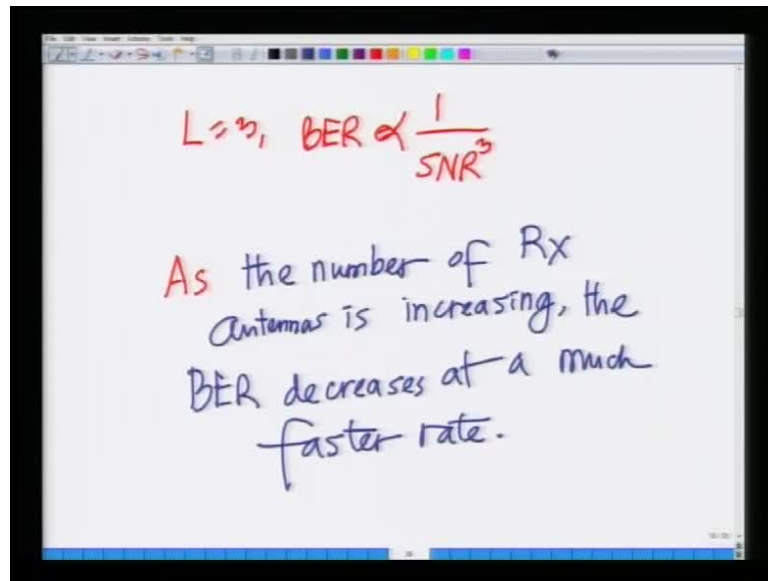

L=1 —  $\frac{1}{2 \text{SNR}} \propto \frac{1}{\text{SNR}}$

L=2 —  $\frac{3}{4} \left(\frac{1}{\text{SNR}}\right)^2 \propto \frac{1}{\text{SNR}^2}$

So, why is this bit error rate decreasing with R x antennas, as I increase the receive number of receive antennas, we have seen that the bit error rate is decreasing. Why is this decrease arising? Let us look at the expression for L antennas for L antennas, we said the bit error rate is given as  $2^{L-1} C_L \frac{1}{2^{L-1}} \left(\frac{1}{\text{SNR}}\right)^L$ . Now, for L equals 1 this is simply as we saw  $\frac{1}{2} \frac{1}{\text{SNR}}$ , which is proportional to one over SNR for L equals to 1 that is one receive antenna.

We have the earlier expression, which is bit error rate equals  $\frac{1}{2 \text{SNR}}$  which is proportional to  $\frac{1}{\text{SNR}}$ . Now, when L equals 2 this expression is as we saw  $\frac{3}{4} \left(\frac{1}{\text{SNR}}\right)^2$ , which is proportional to  $\frac{1}{\text{SNR}^2}$ . So, look at these 2 terms here at L equals to 1 at one receive antenna, this is decreasing bit error rate is decreasing as  $\frac{1}{\text{SNR}}$  with L equals 2 receive antennas, the bit error rate is decreasing as  $\frac{1}{\text{SNR}^2}$  remember at high SNR, SNR square is much larger than SNR hence,  $\frac{1}{\text{SNR}^2}$  is much smaller than  $\frac{1}{\text{SNR}}$ .

(Refer Slide Time: 38:26)

Similarly, for L equals 3 bit error rate equals 1 or is proportional to 1 over SNR cube which means, SNR cube is much larger than SNR square and SNR. So, 1 over SNR cube is much lower than 1 over SNR. Hence, the bit error rate is much lower with 3 antennas and so on and so forth. So, hence as the number of receive antennas is increasing, as the number of receive antennas increasing the exponent of SNR in the denominator is increasing right.

So, as number of receive antennas L is increasing the exponent of SNR in the denominator or the bit error rate is 1 over SNR to the power of L. So, the exponent of 1 over SNR is increasing hence, the bit error rate is decreasing at a much faster rate is increasing the bit error rate B E R decreases at a much faster, as the number of receive antennas are increasing, the bit error rate is decreasing at a much faster rate.

(Refer Slide Time: 40:17)

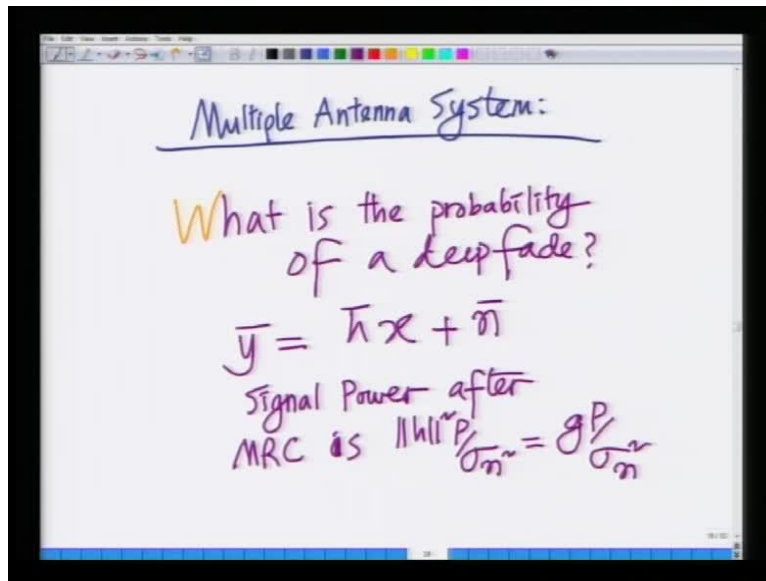

Let us and let me just show you to reinforce this idea, let me just show you a plot of the bit error rate of systems with different numbers of transmit antennas. Let me go here for instance here I have a plot of the bit error rate of a wireless communication systems, with different receive antennas. This blue one here is A W G N that is that is the wire line communication system, this black one here corresponds to L equals 1 receive antenna. This red one corresponds to L equals 2, the red dotted one corresponds to L equals 4 the magenta is L equals 8, and the magenta dotted is L equals 20.

So, you can see as the number of receive antennas keeps increasing progressively, the bit error rate keeps decreasing at a faster and faster rate and it progressively achieves. Remember we said for a wireless communication system, the performance is much worst compared to a wire line or a wired communication system, but now what we see here is that as the number of receive antennas L keeps on increasing the performance of the wireless communication system.

Progressively improves towards that of a wire line communication system, that is with as the as the diversity, or as the number of receive antennas keeps increasing, the bit error rate decreases at a faster and faster rate eventually, approaching the bit error rate decrease of that of a wire line communication system. So, let me go back to my lecture here let me go back to the lecture slide. So, let us understand, why this is arising?

(Refer Slide Time: 42:16)

So, let us look at this multiple antenna system, let us look at this multiple antenna system and let us again ask the question that we asked before. What is the probability of a deep fade in this term in this multiple antenna system, what what is the probability of a deep fade in this multiple antenna system, what is the probability that the system is in a deep fade.

We said that the system model or the receive system model can be expressed as  $\bar{y}$  equals  $\bar{h}$   $x$  plus  $\bar{n}$ , we said the signal power after M R C combining after maximal ratio combining is  $\frac{\|h\|^2 P}{\sigma_n^2}$ , which is also the gain times  $\frac{P}{\sigma_n^2}$ . We said that in this system with multiple receive antennas, the received signal to noise power ratio after maximal ratio combining, or at the output of the M R C, combiner maximal ratio combiner is nothing but  $\frac{\|h\|^2 P}{\sigma_n^2}$ .

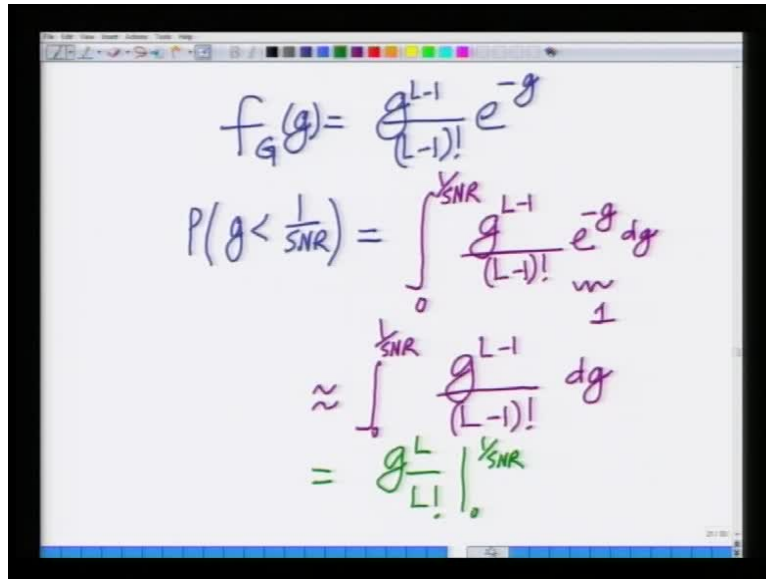

(Refer Slide Time: 44:16)

The image shows a whiteboard with handwritten mathematical expressions. At the top, the SNR is defined as  $SNR = \frac{\|h\|^2 P}{\sigma_n^2}$ . The numerator  $\|h\|^2 P$  is circled in purple and labeled "Signal Power" with a green arrow. The denominator  $\sigma_n^2$  is circled in green and labeled "Noise Power" with a green arrow. Below this, the condition for a deep fade is given as  $\|h\|^2 P < \sigma_n^2$ . This is then simplified to  $gP < \sigma_n^2$  and further to  $g < \frac{1}{SNR}$ , which is enclosed in a blue rectangular box. A red arrow labeled "deep fade:" points from the text to the boxed equation.

Now, the SNR equals norm h square p over sigma n squared, where this is the at the top one is the signal power, the bottom one sigma n squared is the noise power. And we said the system is in a deep fade, when the received power is smaller than the noise power. Remember in the wireless fading channel case, we said the system is in a deep fade when the destructive interfere in such, that the received power at the output is smaller than the noise power. So, in this case the system is in a deep fade when norm h square into p is less than sigma n square, or g times p is less than sigma n square or g is less than 1 over SNR alright, this system we say is in a deep fade, this system with multiple receive antennas is in a deep fade, when the gain g is less than one over SNR.

(Refer Slide Time: 45:50)

$$f_g(g) = \frac{g^{L-1}}{(L-1)!} e^{-g}$$

$$P\left(g < \frac{1}{\text{SNR}}\right) = \int_0^{\frac{1}{\text{SNR}}} \frac{g^{L-1}}{(L-1)!} e^{-g} dg$$

$$\approx \int_0^{\frac{1}{\text{SNR}}} \frac{g^{L-1}}{(L-1)!} dg$$

$$= \frac{g^L}{L!} \Big|_0^{\frac{1}{\text{SNR}}}$$

Now, we also that the distribution of this  $g$  that is the probability distribution of this  $g$  is  $g$  to the power of  $L$  minus 1 divided by  $L$  minus 1 factorial into  $e$  power minus  $g$ . Which means, now I need to find the probability of a deep fade, which is essentially the probability that  $g$  is less than  $1$  over  $\text{SNR}$ . Hence, that probability is given by integrating this probability density functions, between  $0$  and  $1$  over  $\text{SNR}$  similar to what we did in the ray fading channel case, and with distribution  $g$  power  $L$  minus 1 divided by  $L$  minus 1 factorial  $e$  power minus  $g$   $dg$ .

So, I am saying the wireless channel with multiple antennas is in a deep fade, when  $g$  is less than one over  $\text{SNR}$  that probability can be determined by integrating, the probability density functions between the limit  $0$  and  $1$  over  $\text{SNR}$  and the probability density functions is  $g$  power  $L$  minus 1 divided by  $L$  minus 1 factorial times  $e$  power minus  $g$  into  $dg$  integrated between  $0$  and  $1$  over  $\text{SNR}$ .

Now, at high  $\text{SNR}$   $1$  over  $\text{SNR}$  is much small is very small. So,  $e$  power minus  $g$  is approximately equal to  $1$  which means, this integral is approximately  $0$  to  $1$  over  $\text{SNR}$   $g$  power  $L$  minus 1 divided by  $L$  minus 1 factorial  $dg$ . Now, integral  $g$  power  $L$  minus 1 is nothing but  $g$  power  $L$  divided by  $L$ . So, this is  $g$  power  $L$  divided by  $L$  and  $L$  times  $L$  minus 1 factorial is nothing but  $L$  factorial. So, this is  $g$  power  $L$  divided by  $L$  factorial between the limits  $0$  and  $1$  over  $\text{SNR}$ .

(Refer Slide Time: 48:08)

Probability of Deep fade  
 $= \frac{1}{L!} \left(\frac{1}{\text{SNR}}\right)^L$   
with more RX antennas }  
Probability of deep fade decrease significantly!  
 $\propto \left(\frac{1}{\text{SNR}}\right)^L$

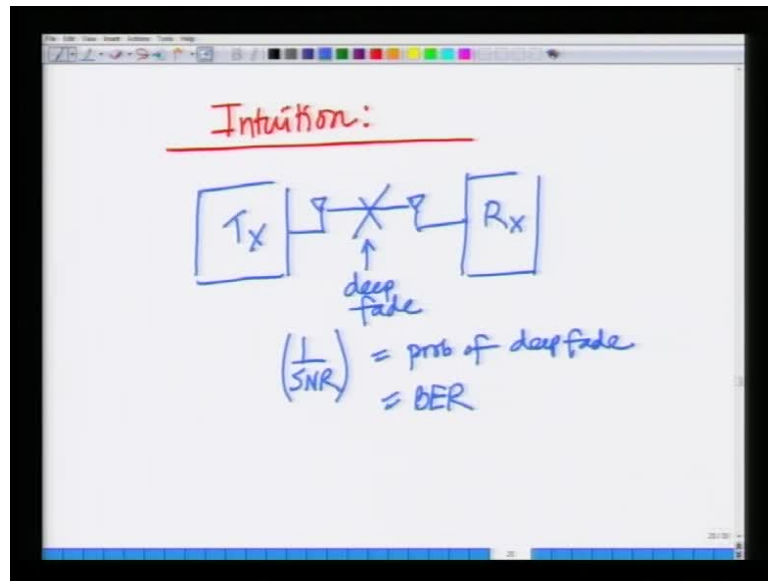

And this at this point it is the probability of deep fade equals 1 over L factorial 1 over SNR to the power L. Look at this, this is the probability of deep fade in this system and it is proportional to one over SNR to the power of L, this is proportional to 1 over SNR to the power of L. Remember in the wireless communication system with the single receive antenna, we said the bit error rate is proportional to 1 over SNR and that is nothing but the probability that that system was in a deep fade.

Now, we are saying that in a wireless communication with system with L antennas, the probability of deep fade is 1 over SNR to the power of L. In fact that is also the bit error rate that is bit error rate is occurring when this system is in deep fade essentially, corresponds to when this system in a deep fade. However, the probability that this system is in a deep fade is now significantly reduced.

Look at this before the probability that the system with one receive antenna was in a deep fade is was 1 over SNR for two antennas, this probability of deep fade will be 1 over SNR square which is significantly reduced with three antennas it is proportional to 1 over SNR cube. As you add more and more receive antennas the probability that this system is in a deep fade becomes decreases progressively that is what this means, this means with more R x antennas probability of deep fade decreases significantly, as you keep increasing the number of receive antennas.

The probability that your system is in a deep fade keeps decreasing at a very fast rate. So, the progressive, the probability that system is in a deep fade decreases when the number of receive antennas and hence since, the probability since deep fade is what is responsible for bit error in wireless communication systems, the probability of bit error also correspondingly decreases as the number of receive antennas increases.

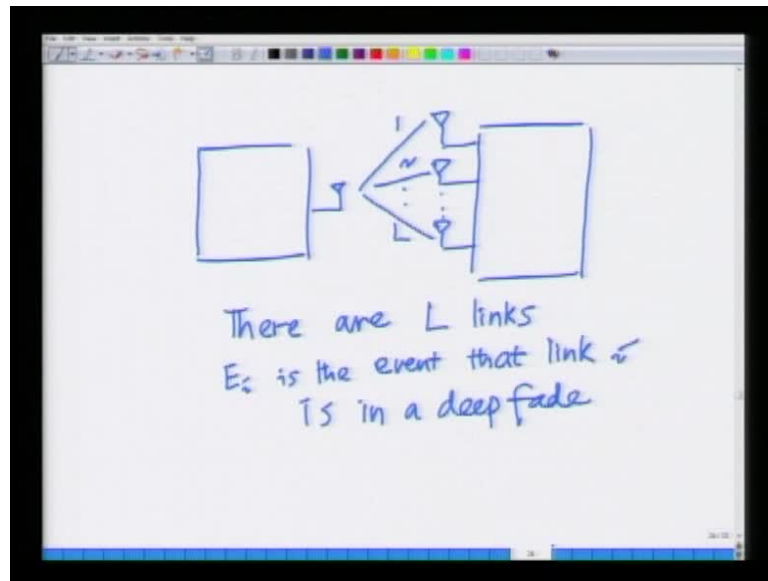

(Refer Slide Time: 50:55)

Now, intuitively why is this happening, what is the intuition, what is the intuition or what is the intuitive reason for this let us look at a system with one transmit antenna, and one receive antenna that is am saying, I have a system with one transmit antenna and one receive antenna there is only one link, we say this example earlier there is only one link the one transmit antenna, one receive antenna there is only one link, if this link was in a deep fade then the bit error rate is high.

And the probability of deep fade is this of this single link is 1 over SNR, 1 over SNR is probability of deep fade, deep fade which is also the bit error rate. We said in a system with one receive antenna and transmit antenna that is a single link, and if this link is in deep fade then the bit error rate is high, the probability with which this single link is in a deep fade is 1 over SNR hence, the bit error rate is 1 over SNR.

(Refer Slide Time: 52:13)

Now, let us look at what happens when we have multiple receive antennas, when we have multiple receive antennas and more specifically, we have  $L$  receive antennas there are  $L$  links in a system, with  $L$  receive antennas, there are  $L$  links between transmit antenna and first receive antenna is link 1 between transmit antenna, second receive antenna is link two so on and so forth between transmit antenna and receive antenna  $L$  is the  $L$  th link.

So, with  $L$  receive antenna there are  $L$  links now, even if one of the links let us say or two of the links, where in a deep fade then I can use the remaining links to transmit my information which means, for this system to be in a deep fade all the  $L$  links have to be in a deep fade because I have  $L$  links for this system to be in a deep fade, all the  $L$  links have to be in a deep fade. So, if  $E_i$  is the event that link  $i$  is in a deep fade.

(Refer Slide Time: 53:43)

The image shows a whiteboard with handwritten mathematical equations. The equations are as follows:

$$P(E_1 \cap E_2 \cap \dots \cap E_L)$$
$$= P(E_1) P(E_2) \dots P(E_L)$$
$$= \left(\frac{1}{\text{SNR}}\right) \times \left(\frac{1}{\text{SNR}}\right) \times \dots \times \left(\frac{1}{\text{SNR}}\right)$$

The final result is circled in red:

$$= \left(\frac{1}{\text{SNR}}\right)^L$$

Next to the circled result, there is a red bracket and the text "L times Deep fade prob:".

What am I looking for the deep fade, the net deep fade event is  $P, E_1$  intersection  $E_2$  intersection  $E_L$  that is I need all the links to be in a deep fade for this system to be in a deep fade. So, to remember all the links are independent, which means  $P$  of  $E_1$  intersection  $E_2$  intersection  $E_L$  is  $P$  of  $E_1$  into  $P$  of  $E_2$  into  $p$  of  $E_L$  which is nothing but one over  $\text{SNR}$ . Now, remember  $P$  of  $E_1$  is the probability that link one is in a deep fade that is  $1$  over  $\text{SNR}$ ,  $P$  of  $E_2$  is nothing but probability link two is in a deep fade that is  $1$  over  $\text{SNR}$ . So, I take product of  $1$  over  $\text{SNR}$   $L$  product of  $1$  over  $\text{SNR}$   $L$  times. Hence, the probability of deep fade is now become  $1$  over  $\text{SNR}$  to the power of  $L$ .

We now have another beautiful interpretation, we have a beautiful interpretation of why this system bit error rate is decreasing as  $1$  over  $\text{SNR}$  to the power of  $L$  that is because I have  $L$  links it means, for the system now to be in a deep fade or the system to result in disruption of communication, I need all the receive antennas to be in a deep fade each receive antenna is in a deep fade with probability  $1$  over  $\text{SNR}$ .

These events are independent which means, the net probability is  $1$  over  $\text{SNR}$  into  $1$  over  $\text{SNR}$  into  $1$  over  $\text{SNR}$   $L$  times hence, the net probability is  $1$  over  $\text{SNR}$  power  $L$ , this is essentially the deep fade probability, which is decreasing as  $1$  over  $\text{SNR}$  to the power of  $L$ . So, we will stop our discussion of this lecture at this point and we will begin again with a closer examination of this point, in the next lecture.

Thank you very much for your attending attention.
