**Properties of Least-Squares Estimate – Mean, Covariance and Distribution.**

Hello, welcome to another module in this massive open online course on estimation for wireless system. So, we are considering currently the maximum like destination of a vector parameter  $\hat{h}$  and we have shown that in the maximum likelihood estimate, which is also the solution or that corresponds to the minimum of the least-squares cost function, this maximum likelihood estimate or the least-squares estimate  $\hat{h}$  is given as,

(Refer Slide Time: 0:37)

The image shows a whiteboard with the following handwritten content:

$$\hat{h} = (X^T X)^{-1} X^T \bar{y}$$

Below the equation, the matrix  $(X^T X)^{-1} X^T$  is written and labeled as the "Pseudo Inverse of X". A green arrow points from this label to the matrix. Another green arrow points from the matrix to the text "ML Estimate" and "LS Estimate".

your  $\hat{h}$  equals  $X^T X^{-1} X^T \bar{y}$ , okay. And this matrix  $X^T X^{-1} X^T$ , we have called this matrix as a pseudo-inverse of  $X$ , remember this is called the pseudo-inverse.

Okay, and this we have also called the ML estimate for the vector parameter, this is your ML estimate or LS, that is least-squares estimate.

(Refer Slide Time: 1:31)

LS Estimate  
→ Properties of ML Estimate

$$\bar{y} = X\bar{h} + \bar{v}$$

System Model.

Gaussian Noise vector

$\bar{y}$  = affine transformation of  $\bar{v} \Rightarrow$  Linear in  $\bar{v}$  + constant Shift

Now, let us explore the properties of this maximum likelihood estimate, let us now explore what we want to do is we want to find, explore the properties of this, we would like to explore the properties of this maximum likelihood estimate which is basically  $\hat{h}$  equals  $X^T X^{-1} X^T Y$ , where  $Y$  bar is of course the vector of observations and the matrix  $X$  is the pilot matrix for this multi-antenna system.

Correct, now recall, they let us go back again to our system model, recall that our system model is  $Y$  bar equals  $H X$  bar +  $V$  bar, this is basically your system model where  $V$  bar is the Gaussian noise vector, remember, this vector contains Gaussian noise samples, so this is a Gaussian noise vector. Now,  $Y$  bar, which is equal to  $H X$  bar +  $V$  bar, it is related in affined fashion to  $V$  bar, that is it is a linear transformation of  $V$  bar, basically  $V$  bar itself, + a constant, shifted by a constant. That is  $H X$  bar. Therefore this is known as affined transformation, right. So,  $Y$  bar is basically related in affined fashion or  $Y$  bar equals to an affined transformation of  $V$  bar, which basically implies linear in  $V$  bar, that this linear formation of  $V$  bar + a constant shift.

Now, affined transformation, now Gaussian variables remain Gaussian under an affined transformation

(Refer Slide Time: 3:48)

$$\bar{y} = X \bar{h} + \bar{v}$$

System Model.

Gaussian Noise vector

$\bar{y} = \text{affine transformation of } \bar{v} \Rightarrow \text{Linear in } \bar{v} + \text{constant shift}$

$\bar{y} = \text{Gaussian vector.}$

implies  $\bar{y}$  is basically equals a Gaussian vector. So, what we are saying is basically the following thing. If I take a Gaussian random variable, if I scale it and if I shift it by another constant, right that is I consider affined transformation of this Gaussian random variable, I basically get another Gaussian random variable. Right, so the Gaussianness remains invariant under affined transformation. Now, I have  $\bar{y}$  equals  $X \bar{h} + \bar{v}$ ,  $\bar{v}$  is Gaussian, so I am taking  $\bar{v}$ , shifting it by  $X \bar{h}$ , therefore  $\bar{y}$  is the Gaussian vector.

(Refer Slide Time: 4:34)

$\bar{y} = \text{Gaussian vector.}$

Observation vector  
 $\bar{y}$  is Gaussian

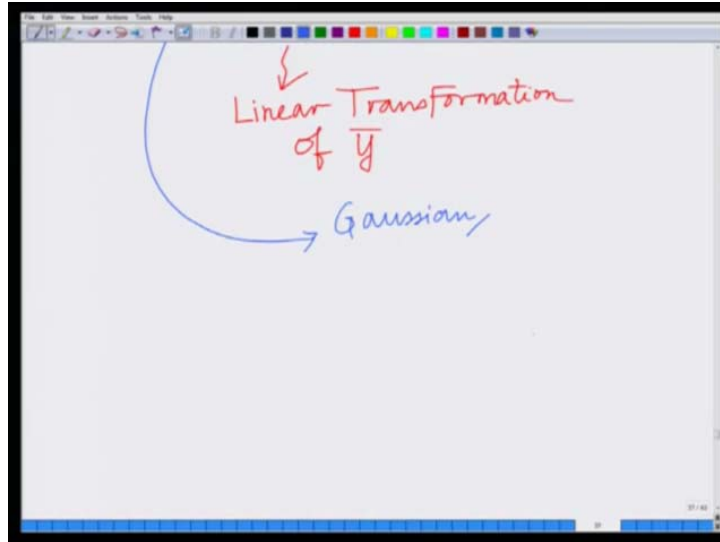

$$\hat{h} = (X^T X)^{-1} X^T \bar{y}$$

Linear Transformation of  $\bar{y}$

So, that is, let us start with that was, that is the observation vector is Gaussian. So,  $\bar{y}$  which is your observation vector, so let me repeat that observation vector  $\bar{y}$  is Gaussian,

now if you look at  $X \hat{h}$ ,  $\hat{h}$  equals  $X^T X^{-1} X^T \bar{y}$ . This is basically a linear transformation of  $\bar{y}$ . What is this, this is a linear transformation, of the vector, this is a linear transformation of the vector  $\bar{y}$

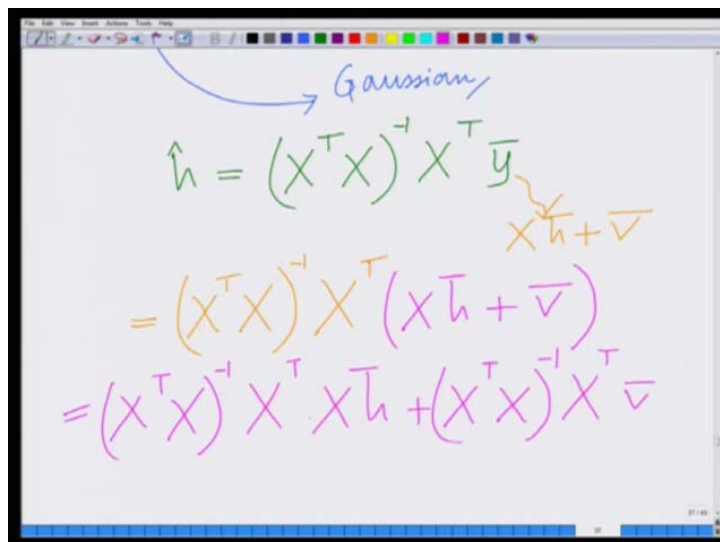

(Refer Slide Time: 5:35)

and hence  $\bar{y}$  is Gaussian, a transformation of a Gaussian vector results in another Gaussian vector  $\hat{h}$  is Gaussian in nature.

Since a transformation of a Gaussian vector results in another Gaussian vector, the estimate  $\hat{h}$  is a Gaussian vector. So, that is the 1<sup>st</sup> thing that we have established. That is  $\hat{h}$  is the estimate of the vector parameter  $h$ , that is  $\hat{h}$  is the Gaussian vector, that is the 1<sup>st</sup> thing.

(Refer Slide Time: 6:11)

Now, 2<sup>nd</sup>, let us look at  $\hat{H}$  equals  $X^T X^{-1} X^T \bar{Y}$  but recall your  $\bar{Y}$  equals  $X \bar{H} + \bar{V}$ , so I substitute that over here now, so I have  $X^T X^{-1} X^T$  times the  $\bar{Y}$ , I will substitute  $X \bar{H} + \bar{V}$  which is basically  $\bar{Y}$ , and now expanding this, I have  $X^T X^{-1} X^T$  times  $X \bar{H} + X^T X^{-1} X^T \bar{V}$ .

(Refer Slide Time: 7:08)

The image shows a whiteboard with handwritten mathematical equations. At the top right, there is a label  $X \bar{h} + \bar{v}$  with an arrow pointing to the expression  $(X^T X)^{-1} X^T (X \bar{h} + \bar{v})$ . The main derivation consists of three lines of equations:

$$= (X^T X)^{-1} X^T (X \bar{h} + \bar{v})$$

$$= \underbrace{(X^T X)^{-1} X^T X}_{I} \bar{h} + (X^T X)^{-1} X^T \bar{v}$$

$$\hat{h} = \bar{h} + (X^T X)^{-1} X^T \bar{v}$$

Now if you look at this quantity over here  $X^T X^{-1} X^T$ , this is identity, therefore I simply have identity times  $\bar{H}$  which is  $\bar{H}$  +  $X^T X^{-1} X^T$  times  $\bar{V}$  and this is your  $\hat{H}$ . So, the least-squares estimator  $\hat{H}$  can be expressed as  $\hat{H}$  equals  $\bar{H}$ , the original parameter, unknown parameter vector + something that depends on noise, that is  $X^T X^{-1} X^T \bar{V}$ .

(Refer Slide Time: 7:43)

Recall  $v(1), v(2), \dots, v(N)$  are IID zero-mean Gaussian RVs.

$$E\{v(1)\} = E\{v(2)\}$$
$$\dots E\{v(N)\} = 0.$$
$$E\{V\} = E\left\{ \begin{bmatrix} v(1) \\ v(2) \\ \vdots \\ v(N) \end{bmatrix} \right\}$$

Now, again recall  $V_1, V_2 \dots$  Up to  $V_N$  are IID 0 mean Gaussian random variables. Implies expected value, since they are 0 mean, expected value of  $V_1$  equals expected value of  $V_2$ , so on and so forth that is expected value of each random variable equals 0.

And therefore, now if I look at the expected value of this vector as a whole, that is if I look at the expected value of this Gaussian vector  $V$  bar, that is the noise vector  $V$  bar, that is equal to basically your expected value of your vector comprising of components  $V_1, V_2 \dots$  Up to  $V_N$

(Refer Slide Time: 9:01)

$$\dots E\{v(N)\} = 0.$$
$$E\{V\} = E\left\{ \begin{bmatrix} v(1) \\ v(2) \\ \vdots \\ v(N) \end{bmatrix} \right\}$$
$$= \begin{bmatrix} E\{v(1)\} \\ E\{v(2)\} \\ \vdots \\ E\{v(N)\} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix} = 0_{N \times 1}.$$

which is basically, now if I take the expected value inside, that is nothing but the expected value of  $V_1$ , expected value of  $V_2$ , so on expected value of  $V_N$  and each of these is basically 0, so this is the  $N$  dimensional 0 vector. And this is fairly natural again, that is what we are saying is if you look at the noise vector, it is the noise components  $V_1, V_2, \dots$  Up to  $V_N$ , each of these Gaussian noise components has 0 mean, therefore the expected value of the vector  $\bar{V}$  is 0. That is it is the 0 vector.

(Refer Slide Time: 9:53)

The image shows a whiteboard with handwritten mathematical derivations. The top part shows the expected value of a noise vector  $\bar{V}$  as a column vector of zeros. The bottom part shows the derivation of the expected value of the least squares estimate  $\hat{h}$ .

$$= \begin{bmatrix} E\{V(1)\} \\ E\{V(2)\} \\ \vdots \\ E\{V(N)\} \end{bmatrix} = \begin{bmatrix} 0 \\ 0 \\ \vdots \\ 0 \end{bmatrix} = 0_{N \times 1}$$

$$\hat{h} = \bar{h} + (X^T X)^{-1} X^T \bar{v}$$

$$E\{\hat{h}\} = E\{\bar{h} + (X^T X)^{-1} X^T \bar{v}\}$$

$$= \bar{h} + E\{(X^T X)^{-1} X^T \bar{v}\}$$

Now, I can use this to simplify the expected value of our estimate  $\hat{h}$ , recall that  $\hat{h}$  equals  $X$  transpose  $X$  inverse  $X$  transpose, that is equals your  $\hat{h}$  equals  $\bar{h}$  +  $X$  transpose  $X$  inverse  $X$  transpose  $\bar{V}$  which means expected value of  $\hat{h}$  equals expected value of  $\bar{h}$  +  $X$  transpose  $X$  inverse  $X$  transpose  $\bar{V}$ . Which is basically nothing but, now  $\bar{h}$  is a constant, so I take it outside,  $\bar{h}$  + expected value of  $X$  transpose  $X$  inverse  $X$  transpose  $\bar{V}$  and now again, the pilot matrix  $X$  is constant, so I can move the expectation inside.

(Refer Slide Time: 10:55)

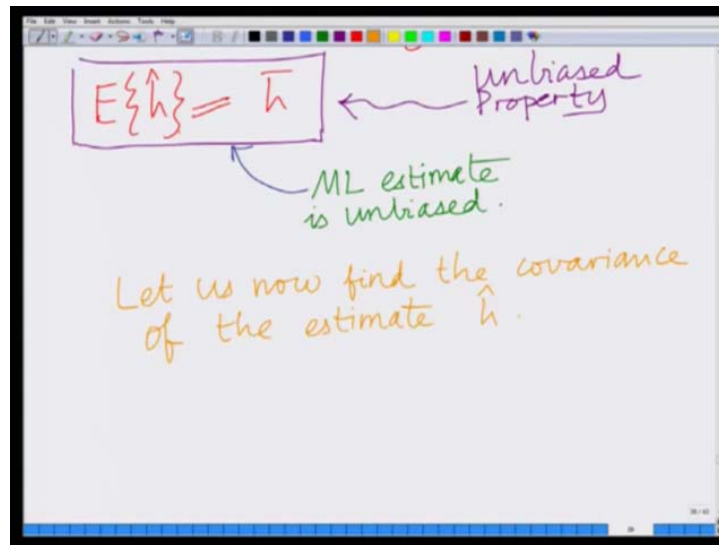

The image shows a whiteboard with handwritten mathematical derivations. At the top, the equation  $= \bar{h} + E\{(X^T X)^{-1} X^T v\}$  is written in green. Below it, the equation  $= \bar{h} + (X^T X)^{-1} X^T E\{v\}$  is written in blue, with  $E\{v\}$  underlined and labeled  $\bar{0}_{N \times 1}$  below it. The next line shows  $= \bar{h} + (X^T X)^{-1} X^T \bar{0}$  in red, with a red '0' written below the  $\bar{0}$ . At the bottom, a purple box contains the equation  $E\{\hat{h}\} = \bar{h}$ , with an arrow pointing to it from the text "unbiased Property" written in purple.

I have  $X^T X^{-1} X^T$  expected value of  $\bar{v}$  but the expected value of  $\bar{v}$  is the 0 vector, that is  $N \times 1$  zero vector, hence as a result of that basically, this quantity, which is  $X^T$ , so let me just write that down, this is  $\bar{h} + X^T X^{-1} X^T \bar{0}$ , this quantity is 0, therefore what we have, again similar to what we have seen many times before that is your expected value of the vector estimate  $\hat{h}$  equals  $\bar{h}$  and this is basically your unbiased property. That is what we are saying is something very interesting and which we already said before in the context of a scalar estimate that is  $\hat{h}$  is the estimate and it is a random quantity, remember, it is not deterministic quantity, remember we have already said that  $\hat{h}$  is a Gaussian, is Gaussian in nature, it is a Gaussian vector.

However, if I look at the average value of  $\hat{h}$ , that is expected value of  $\hat{h}$ , that is equal to  $\bar{h}$ , that is expected value is basically equal to the true value of the underlying unknown parameter. Therefore such an estimator is known as an unbiased estimator and the estimate is known as the unbiased estimate. So, this maximum likelihood estimate or the least-squares estimate is unbiased in nature.

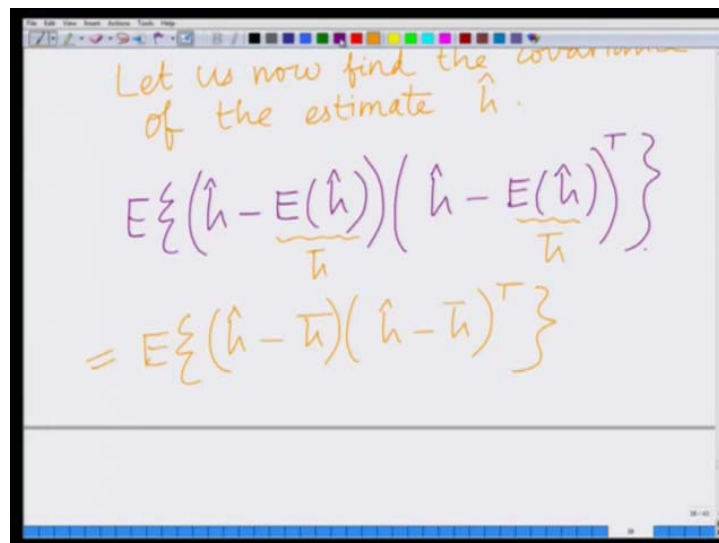

(Refer Slide Time: 12:29)

That is the 1<sup>st</sup> thing that we have explained established. So your ML or basically least-squares estimates, the ML or least-squares estimate is unbiased, that is the 1<sup>st</sup> thing. Now what we want to do, the 2<sup>nd</sup> thing that we have to do is find the **various** variance or the covariance, since this is a vector, right for a scalar random variable, we find the various, scalar estimate we find the variance.

(Refer Slide Time: 13:32)

Since this is a vector, let us find the covariance of the estimate. So, let us now find the covariance of the estimate. Let us now find the covariance of the estimate  $\hat{h}$  that is the covariance of the estimate is defined as, remember  $\hat{h}$  - the expected value of  $\hat{h}$  times

its transpose,  $\hat{H}$  - expected value of  $\hat{H}$  slightly  $\hat{H}$  - expected value of  $\hat{H}$  transpose, I now realise that expected value of  $\hat{H}$  is basically your vector  $\bar{H}$ , because this vector is, the estimate is unbiased, so basically that is basically nothing but your expected value of  $\hat{H}$  -  $\bar{H}$  times  $\hat{H}$  -  $\bar{H}$  transpose. Now we have already seen that  $\hat{H}$ , look at this,  $\hat{H}$  equals  $\bar{H} + X^T X^{-1} X^T \bar{V}$ , so what I have here is basically,

(Refer Slide Time: 14:40)

The image shows a whiteboard with handwritten mathematical equations. At the top, the equation  $\hat{h} - \bar{h} = (X^T X)^{-1} X^T \bar{v}$  is written in blue. A blue arrow points from this equation down to the next line, which is the covariance matrix expression:  $\text{Covariance} = E\left\{ (X^T X)^{-1} X^T \bar{v} (X^T X)^{-1} X^T \bar{v}^T \right\}$ . Below this, the expression is simplified to  $= E\left\{ (X^T X)^{-1} X^T \bar{v} \bar{v}^T X (X^T X)^{-1} \right\}$ , with the terms  $(X^T X)^{-1} X^T \bar{v} \bar{v}^T X (X^T X)^{-1}$  written in orange.

I will use the property  $\hat{H}$  or let me use the property  $\hat{H}$  equals  $\bar{H} + X^T X^{-1} X^T \bar{V}$  which basically implies that, now if you look at this, this basically implies  $\hat{H} - \bar{H}$  equals  $X^T X^{-1} X^T \bar{V}$ .

And now if I substitute that in this expression over here, I will get the covariance is equal to expected value of  $\hat{H} - \bar{H}$ , that is  $X^T X^{-1} X^T \bar{V}$  times its transpose, that is  $X^T X^{-1} X^T \bar{V} \bar{V}^T X (X^T X)^{-1}$ . And now I can simplify this quantity, this quantity can be simplified as follows, this is the expected value of, well, the 1<sup>st</sup> quantity I can take it as it is, it is  $X^T X^{-1} X^T \bar{V}$ . The 2<sup>nd</sup> quantity, transpose of that is  $\bar{V} \bar{V}^T X (X^T X)^{-1}$  transpose which means  $X (X^T X)^{-1} X^T \bar{V} \bar{V}^T$ , that is again this is symmetric matrix, the inverse is also symmetric, therefore the transpose is itself.

(Refer Slide Time: 16:19)

The whiteboard shows the following equation and notes:

$$= (X^T X)^{-1} X^T E \{ \bar{V} \bar{V}^T \} X (X^T X)^{-1}$$

Covariance of noise vector  $\bar{V}$   
→ zero mean IID Gaussian noise elements.  
 $V(1) V(2) \dots V(N)$  of variance  $\sigma^2$

Now I can move the expectation operator inside, when I move the expectation operator inside, what I have is basically, I have your X transpose X inverse expected V V bar times X transpose X inverse, and now this expected V V bar transpose, this is nothing but covariance of the noise. Remember, expected V bar V bar transpose is the covariance of the noise vector V bar and remember again we are considering 0 mean IID Gaussian noise elements V1, V2... Up to VN, which means the covariance matrix is Sigma square times identity. That is also something that we have seen before, remember this is we are considering 0 mean IID Gaussian noise aliments V1, V2... Up to VN of variance that is each noise sample has mean 0, variance Sigma square and these noise samples are independent, implies,

(Refer Slide Time: 18:05)

The whiteboard shows the following equation and notes:

$$= (X^T X)^{-1} X^T \sigma^2 I X (X^T X)^{-1}$$

Covariance of noise vector  $\bar{V}$   
→ zero mean IID Gaussian noise elements.  
 $V(1) V(2) \dots V(N)$  of variance  $\sigma^2$   
 $\Rightarrow E \{ \bar{V} \bar{V}^T \} = \sigma^2 I$

which implies the covariance expected  $\bar{V} \bar{V}^T$  is equal to  $\sigma^2$  times identity.

That is the noise covariance expected  $\bar{V} \bar{V}^T$  considering 0 mean IID noise samples of mean 0 and variance  $\sigma^2$  is basically  $\sigma^2$  times identity. And now I substitute that in this expression for the covariance of the estimate  $\hat{h}$  to simplify it further. And now once you substitute that things, I see it has a nice form, this is basically reduces to equal to  $X^T X^{-1} X^T$  times the covariance which is  $\sigma^2$  times identity times  $X X^T X^{-1}$

(Refer Slide Time: 18:58)

The image shows a whiteboard with handwritten mathematical equations. The top line is partially obscured but shows  $= (X^T X)^{-1} \sigma^2 I (X^T X)^{-1}$ . The second line is  $= \sigma^2 (X^T X)^{-1} X^T X (X^T X)^{-1}$ , with  $X^T X$  underlined in green. The third line is  $= \sigma^2 (X^T X)^{-1}$ , with  $(X^T X)^{-1}$  underlined in green. Below this, the text "Covariance of Estimate  $\hat{h}$ " is written in green, with an arrow pointing to the underlined term.

and now you can clearly see I can bring the  $\sigma^2$  outside, that is a scalar quantity and identity times any matrix is the matrix itself.

So, this reduces to  $X^T X X^T X^{-1}$ , now you can see that this I have an  $X^T X^{-1}$ , I have an  $X^T X$ , so basically this is identity, so this is  $\sigma^2$  times what I am left with is  $X^T X^{-1}$  and this is the covariance of the estimate. What is this, this is basically your covariance of the estimate  $\hat{h}$  of the vector parameter. And finally to summarise, we already said 3 things,  $\hat{h}$  is a Gaussian parameter,  $\hat{h}$  has mean, this is an unbiased estimate, that is expected value of  $\hat{h}$  is parameter vector  $\bar{h}$  and its covariance is  $\sigma^2 X^T X^{-1}$ , therefore now I can neatly summarise this as, is basically it is Gaussian, it is a constant vector.

(Refer Slide Time: 20:05)

The whiteboard shows the following content:

$$= \frac{\sigma^2 (X^T X)}{\text{Covariance of Estimate } \hat{h}}$$
$$\hat{h} \sim \mathcal{N}(\bar{h}, \sigma^2 (X^T X)^{-1})$$

The word "Gaussian" is written above the distribution equation.

We denote it by N with mean  $\bar{h}$  covariance  $X^T X$  inverse. Alright, so this summarises the behaviour of the estimator which is Gaussian with mean  $\bar{h}$  and covariance  $\sigma^2 X^T X$  inverse. And now also realise something interesting that diagonal elements of the covariance matrix correspond to the variances of the components of the vector estimate.

(Refer Slide Time: 20:46)

The whiteboard shows the following content:

$$\hat{h} \sim \mathcal{N}(\bar{h}, \sigma^2 (X^T X)^{-1})$$

Variance of  $i^{\text{th}}$  coefficient  $\hat{h}_i$

$$E\{(\hat{h}_i - h_i)^2\} = [\sigma^2 (X^T X)^{-1}]_{i,i}$$
$$= \sigma^2 [(X^T X)^{-1}]_{i,i}$$

That is, if you look at the  $i^{\text{th}}$  estimate, variance of the  $i^{\text{th}}$  element, variance of the  $i^{\text{th}}$  coefficient  $\hat{h}_i$ , that is, rather variance or the estimate of the  $i^{\text{th}}$  coefficient, that is expected value of  $\hat{h}_i - h_i$  square, this is that  $i^{\text{th}}$  diagonal element of the covariance

matrix, this is Sigma square X transpose X inverse, that is the I, Ith element. That is Ith diagonal element or the I, Ith element of this matrix which is basically nothing but, Sigma square is a constant, so you can bring that out, that is I take the Ith diagonal element of this matrix.

(Refer Slide Time: 21:46)

The image shows a whiteboard with handwritten mathematical equations. At the top, it says "Variance of  $i^{\text{th}}$  coefficient  $\hat{h}_i$ ". Below this, the equation is written as  $E\{(\hat{h}_i - h_i)^2\} = [\sigma^2 (X^T X)^{-1}]_{i,i}$ . A second line shows  $= \sigma^2 [(X^T X)^{-1}]_{i,i}$ . A yellow arrow points from the text "Variance of estimate of  $i^{\text{th}}$  coefficient" at the bottom to the first equation.

This is, what is this, this is the variance of the estimate of the Ith coefficient. This is the variance of the estimate of the Ith coefficient in the vector parameter H hat. Alright, so what we have seen in this module is basically we have looked at the least-squares or the maximum likelihood estimate H hat which is equal to X transpose X inverse times X transpose Y bar and we have simplified, we have explored the properties of this vector estimate and similar to before, we have said that 1<sup>st</sup> this vector estimate, it is a Gaussian vector, remember, unlike the scalar estimates that we have considered previously, now we are considering a estimate, a vector estimate or an estimate of a vector parameter. So, what we have is a Gaussian vector which is unbiased, which means the average value of this estimate a chat is basically the underlying parameter H bar.

At the covariance is basically given by Sigma square X transpose X inverse, where X remember we said is the pilot matrix. Alright, and finally we have also said the variance of the Ith, the variance in the estimate of the Ith coefficient is given by the Ith diagonal element or I, Ith element of this covariance matrix. Alright. So, that basically succinctly summarises the properties of this maximum likelihood estimate and we will explore other aspects in the subsequent modules, thank you very much.
