Likelihood Function and Maximum Likelihood (ML) Estimate

Hello, welcome to another module in this massive open online course on Estimation or Estimation theory for Wireless Communication. And in the previous module we had started looking at the basic model for Estimation.

We had considered a sensor network and then noisy observation model for the Sensor network in which our observation.

(Refer Slide Time: 00:39)

The image shows a whiteboard with handwritten mathematical expressions. At the top, the equation $y = h + v$ is written in green, with a blue arrow pointing from v to $\mathcal{N}(0, \sigma^2)$. Below this, the text "Observation = parameter + noise" is written in blue. A blue arrow points from this text to $\mathcal{N}(h, \sigma^2)$. At the bottom, the Probability Density Function (PDF) of the observation y is written in purple: $f_Y(y) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{1}{2\sigma^2}(y-h)^2}$.

Remember we have our observation y which is equal to the parameter h + the noise, so this is your observation at the Centre which is equal to the parameter that is denoted by h + the noise that is denoted by... And in addition we have seen then this v is Gaussian with mean 0 Sigma square.

Then this y is also Gaussian with mean given by the unknown parameter h and variance Sigma square. Therefore, Probability Density Function of this observation f_y of y that is the PDF of this observation y .

That is the random variable y is $\frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{1}{2\sigma^2}(y-h)^2}$, this is the Probability Density Function of the observation y at the

Sensor node corresponding to the parameter h and Gaussian noise v with mean 0 at variance or power σ^2 . So this is what we have seen in the previous module.

Now let us extend this module further, let us extend this to a scenario where a sensor node is making multiple measurements in time. For now I would like to consider our sensor node scenario. So let us go back to our sensor network, our sensor node which is now making multiple measurements. So our sensor node which is making multiple, so our sensor node is making...

(Refer Slide Time: 02:17)

MEASUREMENTS h
SENSOR $y(1), y(2), \dots, y(N)$
Time

$$\begin{aligned} y(1) &= h + v(1) \\ y(2) &= h + v(2) \\ &\vdots \\ y(N) &= h + v(N) \end{aligned}$$

$\mathcal{N}(0, \sigma^2)$

Again remember measurements, but this time it is making multiple measurements of this parameter h in time. So we have measurements y_1, y_2, y_N and these are the multiple measurements being made at different time instance 1, 2 up to and so we have the measurements y_1, y_2, y_N capital N measurements being made a capital N time instance.

And interestingly now you can also consider this as a sensor network with multiple sensor nodes with capital N sensor nodes making capital N measurements, right. Instead of considering these such as single sensor making N measurements in time when can also consider this as N sensors making multiple measurements at a single instant of time.

So this so this basically captures both the single sensor and also a multiple sensor scenario for the measurement and subsequent estimation of the parameter h . Now therefore, these measurements can be modeled as each measurement is basically a noisy observation y_1 equals $h + v_1$, y_2 equals the parameter $h + v_2$.

So on and so forth y_N , the N th measurement is the parameter $h + v_N$ and similarly we also assume that all these noise elements v_1, v_2, v_N are noise with 0 mean and variance σ^2 , so each measurement y_K at the K th instant of time is $h + v_K$ where K can range from 1 to N , we have N instant of time.

So in general I can represent this as the K th measurement y_K equals $h + v_K$ where K denotes the K th instant the K th instant of time.

(Refer Slide Time: 04:47)

The image shows a whiteboard with handwritten mathematical expressions. At the top, the equation $y(k) = h + v(k)$ is written in orange. A blue arrow points from the text " k^{th} instant of Time" to the k in the equation. Below this, the Probability Density Function (PDF) is written as $f_{Y(k)}(y(k)) = \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{1}{2\sigma^2}(y(k)-h)^2}$. A green arrow points from the text "PDF of each individual observation $y(k)$ " to the entire PDF equation.

And naturally the Probability Density Function corresponding to y_K is f of y_K of your observation y_K is again the same. It is Gaussian with mean given by the parameter h and variance σ^2 .

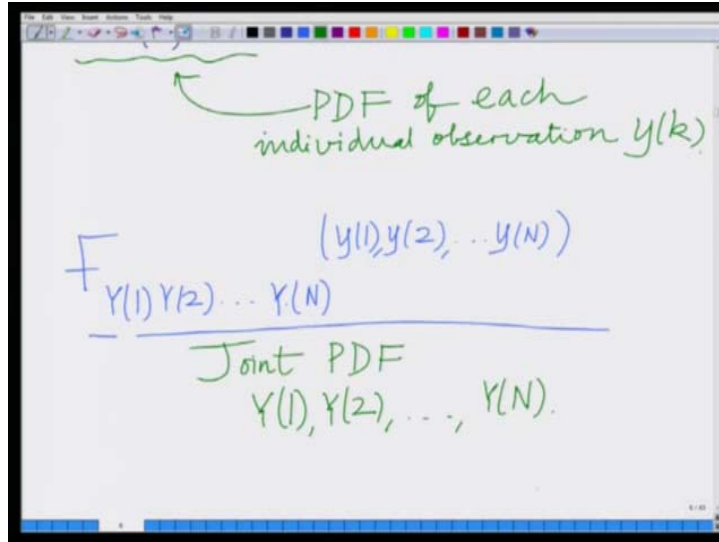

So this is given by the Probability Density Function which is 1 over square root of $2\pi\sigma^2$ e raise to $-\frac{1}{2\sigma^2}(y_K - h)^2$, this is the Probability Density Function, this is the PDF of each individual of each individual observation y of K .

This is the PDF of each individual observation y of K , we are saying the same thing that is each individual observation made by the sensor at time instant K is a Gaussian, has a Gaussian Probability Density Function mean with given by the unknown parameter h and variance given by the variance of the noise v_k which is σ^2 .

Now what we are interested is we want to come up with the joint density of the of the observation y_1, y_2 up to y_N . We have to come up with a joint PDF or the joint Probability

Density Function of the observation y_1, y_2 up to y_N which is represented by f subscript y_1, y_2, \dots, y_N of y_1, y_2 up to y_N .

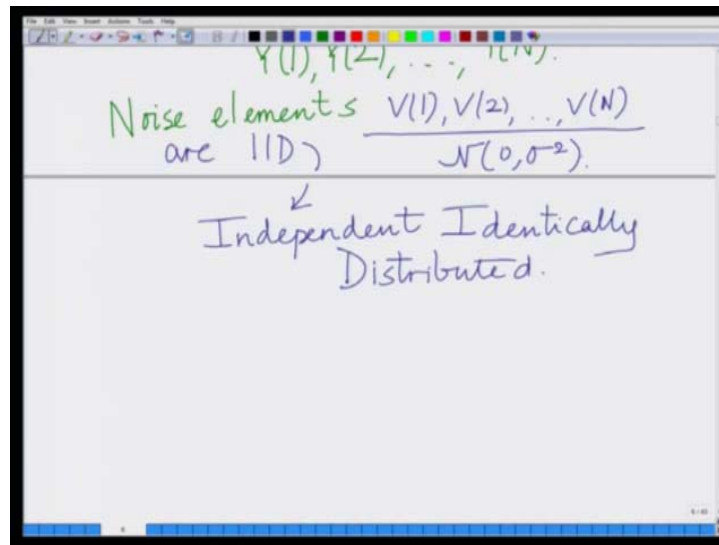

(Refer Slide Time: 06:39)

We have to come up with the joint Probability Density Function, this is a joint PDF of these observations y_1, y_2 up to y_N and towards this and we will make a simplifying assumption to come up with a joint probability density function, we are going to assume initially that these noise elements v_1, v_2, \dots, v_N are IID that is these are Independent Identically Distributed.

So the noise elements, the assumption that we are going to make is towards this end to develop the joint Probability Density Function. The noise elements or the noise samples v_1, v_2, \dots, v_N are IID.

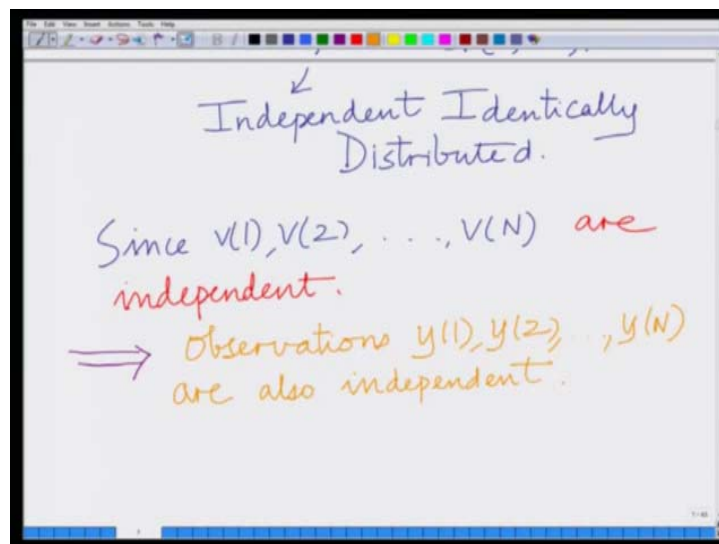

(Refer Slide Time: 07:55)

What do we mean by IID that is, they are independent and identically, they are Independent Identically Distributed. That is, all of these are identical distributed, that is, what we have already early on, that is Gaussian with mean 0 variance Sigma square.

And also they are Independent, right. These noise samples v_1, v_2, v_N are Independent. Which means observations y_1, y_2, y_N are also independent, so the observations y_1, y_2, y_N of the noise sample v_1, v_2, v_N are dependent. The observations y_1, y_2, y_N are Independent and therefore what we have, since v_1, v_2 noise samples v_1, v_2 up to v_N are Independent.

(Refer Slide Time: 08:56)

This implies that basically your observations y_1, y_2 up to y_N are also independent. In fact, they are Independent identically distributed with mean μ and variance σ^2 . Therefore, the probable joint Probability Density Function of the observation is of the observations y_1, y_2, y_N is the product of the individual Probability Density Function corresponding to the observation because the observations are Independent.

And that gives us an important result.

(Refer Slide Time: 10:11)

The image shows a whiteboard with the following handwritten mathematical derivation:

$$f_{Y(1), Y(2), \dots, Y(N)}(y(1), y(2), \dots, y(N))$$

$$= f_{Y(1)}(y(1)) \times f_{Y(2)}(y(2)) \times \dots$$

$$\dots \times f_{Y(N)}(y(N)).$$

That is, the joint Probability Density Function which we are talking about before f of y_1, y_2 up to y_N of y_1, y_2 up to y_N . This is equal to the product of the individual Probability Density Function that is f of y_1 of y_1 times f of y_2 of y_2 times f of N of y_N that is, this is the product of the individual Probability Density Function.

Product of individual Probability Density Function of the observation and we know what is the individual Probability Density Function of each observation that is...

(Refer Slide Time: 11:31)

Handwritten whiteboard content:

$$\dots \times \prod_{Y(N)} (y(N))$$

Product of the individual Probability Density Functions of observations

$$= \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{1}{2\sigma^2} (y(1))}$$

1 over 2 pie Sigma square, square root of 2 pie Sigma square e raise to - 1 over 2 Sigma square times y 1 - h whole square...

(Refer Slide Time: 11:50)

Handwritten whiteboard content:

$$= \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{1}{2\sigma^2} (y(1)-h)^2} \times$$
$$\times \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{1}{2\sigma^2} (y(2)-h)^2} \times \dots$$
$$\dots \times \frac{1}{\sqrt{2\pi\sigma^2}} e^{-\frac{1}{2\sigma^2} (y(N)-h)^2}$$
$$= \left(\frac{1}{2\pi\sigma^2}\right)^{N/2} \cdot e^{-\frac{1}{2\sigma^2} \sum_{k=1}^N (y(k)-h)^2}$$

Times the product times the product 1 over square root 2 pie Sigma square e raise to - 1 over 2 Sigma square y 2 - h square times 1 over square root of 2 pie Sigma square e rise to - 1 over 2 Sigma square y N - h y N - h whole square. This is the product of the individual Probability Density Function corresponding to the observations y 1, y 2 up to y N.

And now simplifying this product of the individual Probability Density Function, you can clearly see that this is given as 1 over, that is collecting 1 over the square root of 2 pie Sigma square terms, I have 1 over 2 pie Sigma square raise to the power N by 2 e raise to - 1 over 2 Sigma square submission, all the expressions all the terms in the exponent will add up K equals 1 to N submission K equals 1 to N y K - h whole square.

And this is your joint Probability Density Function.

(Refer Slide Time: 13:48)

$$= \left(\frac{1}{2\pi\sigma^2} \right)^{N/2} \cdot e^{-\frac{1}{2\sigma^2} \sum_{k=1}^N (y(k) - h)^2}$$

Joint PDF of Observations.

Parameter h is UNKNOWN.

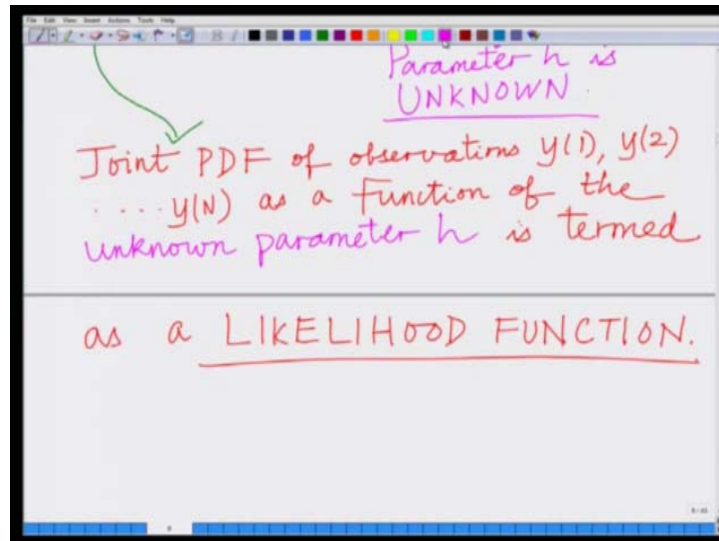

This is the joint PDF of this is the joint PDF of the observation y_1, y_2 up to y_N . And now [we] I would like to bring to your attention an important point, note that while deriving this joint PDF we have ignored the facts so far that this parameter h is an unknown parameter. This is the parameter that we are trying to estimate at the sensor node or the fusion centre.

This parameter h as I pointed out to you also in the previous module that this parameter h is unknown. So to realize that in this, in our Probability Density Function, this parameter h is unknown. This parameter h is unknown and therefore one has to estimate this parameter h , this is known as Parameter Estimation.

This is what I pointed out to you in the previous module that is estimating this parameter h . That is finding on what this computing the value of this parameter h is termed as Parameter Estimation. And this probability joint Probability Density Function as a function of the unknown parameter h , because there is a parameter which is unknown, as a function of the unknown parameter h , this is known as a Likelihood Function.

And this is the important point, and one of the central points. I would like to point out in the entire framework of estimation theory. That is the Probability Density Function viewed as the function of the unknown parameter h is termed as Likelihood Function. That is the the joint Probability Density Function of the observation.

(Refer Slide Time: 15:40)

Let me put it this way, the joint PDF of your observations y_1, y_2 up to y_N as a function of the unknown parameter H is termed the Likelihood Function. This is the Likelihood Function corresponding to the, this is the Likelihood Function which is basically the joint Probability Density Function of the observations y_1, y_2, y_N which is viewed as a function of this unknown parameter h .

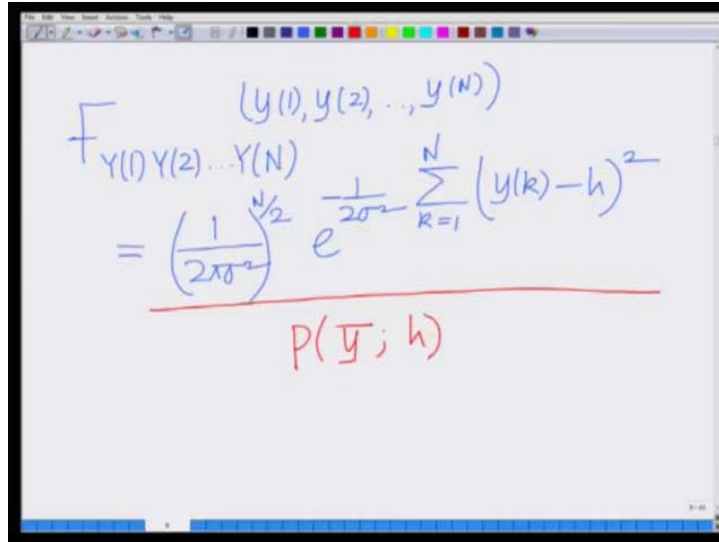

This is known as the Likelihood Function, Likelihood Function of the parameter h . The argument is the unknown parameter h in a certain sense, this represents for each value h this represents the likelihood corresponding to the unknown parameter h .

Right and we would like to use this Likelihood Function to find the estimate of the parameter h and therefore one natural framework to find an estimate of the parameter h is to find that value of h for which the likelihood is maximum and that is known as the Maximum Likelihood Estimate. And this is an important aspect of estimation or this is an important concept in estimation.

We have derived the likelihood function of the unknown parameter h . Now we would like to maximize this Likelihood Function and find out that value of h which maximizes this Likelihood Function and that is known as the Maximum Likelihood Estimate. So what we

would like to do is first let us look at this likelihood function, right. What is this Likelihood Function?

(Refer Slide Time: 18:30)

The image shows a whiteboard with handwritten mathematical equations. At the top, the likelihood function is written as $f_{Y(1)Y(2)\dots Y(N)}(y(1), y(2), \dots, y(N))$. Below this, it is equated to $\left(\frac{1}{2\pi\sigma^2}\right)^{N/2} e^{-\frac{1}{2\sigma^2} \sum_{k=1}^N (y(k)-h)^2}$. A horizontal red line is drawn below the equation, and the expression $P(\bar{y}; h)$ is written in red below the line.

This Likelihood Function is your joint PDF that is f of y_1, y_2 up to y_N y_1, y_2 up to y_N which is equal to 1 over square root of 2π Σ square e raise to -1 over 2 Σ . In fact, this is 1 over 2π Σ square raise to the power of N by 2 e raise to -1 over 2 Σ square K equals 1 to N $y_K - h$ Whole Square. This is a function of the unknown parameter h .

Now what I am going to do, I am going to define this as the as the likelihood of the observations \bar{y} parameterized by h where \bar{y} is observation vector \bar{y} is observation vector. Remember, we have multiple observations so \bar{y} is the observation vector y_1, y_2 up to y_N . So this is my basically my observation vector.

(Refer Slide Time: 19:40)

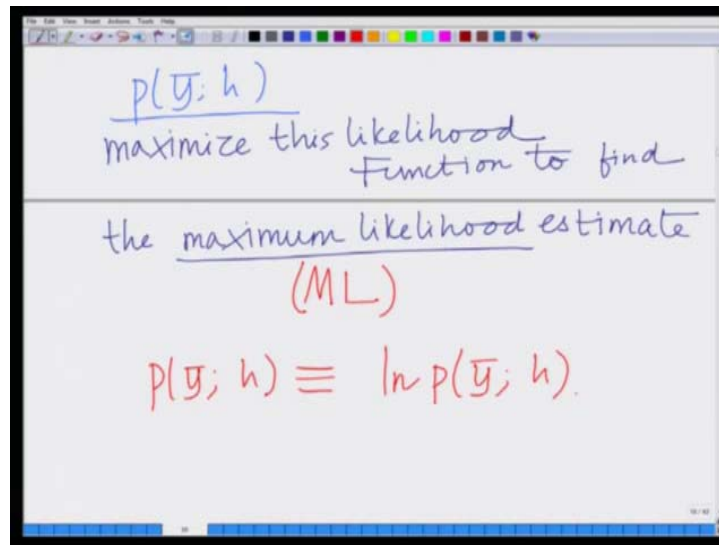

The image shows a whiteboard with handwritten mathematical expressions and labels. At the top, the expression $\frac{1}{2\sigma^2} \sum_{k=1}^N (y(k) - h)$ is written, with a $\frac{1}{2}$ written above the $2\sigma^2$ term. Below this, the expression is equated to $\left(\frac{1}{2\sigma^2}\right)^{N/2} e^{-\frac{1}{2\sigma^2} \sum_{k=1}^N (y(k) - h)}$. A horizontal red line separates this from the definition of the Likelihood Function below. The Likelihood Function is written as $P(\bar{y}; h)$. A blue arrow points from the label 'likelihood' to $P(\bar{y}; h)$. A blue arrow points from the label 'observation vector' to \bar{y} . A blue arrow points from the label 'parameter' to h . Below this, the observation vector is defined as $\bar{y} = \begin{bmatrix} y(1) \\ y(2) \\ \vdots \\ y(N) \end{bmatrix}$. A green arrow points from the label 'observation vector' to this vector.

This contains all observation. This \bar{y} is my observation vector and p of \bar{y} h denotes this is the likelihood, what is this; this is the Likelihood Function of the observation vector and this is parameterized by h denotes, this is parameterized h , the terminology that is used is p . That is, we have this observation vector \bar{y} which is of length N which contains observation y_1, y_2 up to y_N .

And p of \bar{y} semi colon h remember it is not a,, it is a semi-colon h which denotes or which signifies the Likelihood Function of the observation vector \bar{y} parameterized by this unknown parameter h . That is, p of \bar{y} h yeah, so this is the likelihood function of the observation vector \bar{y} which is parameterized by h .

And now let us look at this thing, this like Likelihood Function; we have derived the expression for this Likelihood Function. Now as we said this basically, this is the Likelihood Function which corresponds to the likelihood of observation vector parameterized by h and now what we would like to do is we would like to maximize this Likelihood Function.

(Refer Slide Time: 21:24)

p of \bar{y} parameterized by h , this is your Likelihood Function. What we would like to do is we would like to maximize this maximize this Likelihood Function to find the estimate which is termed as the Maximum Likelihood Estimate. In short, this is also denoted by ml . So we would like to maximise the Likelihood Function to find the Maximum Likelihood Estimate of the unknown parameter h .

This maximum likelihood, this concept of maximum likelihood is also abbreviated as ml which denotes the maximum likelihood. Now let us look at this, instead of maximizing p of \bar{y} parameterized by h , I can also maximise that is, maximising this is equivalent to maximising the log of p of \bar{y} parameterised by h . Because if the function maximum, the Logarithm is also maximum because the log is a monotonically increasing function.

We are talking about the natural logarithm. Let me denote this by \ln that is log to the base e . When a function is maximum, its logarithm is also maximum. So function is maximise, instead of maximising the function, finding the point where the function is maximum, it is convenient in this problem since we have an exponential, we would like to find the parameter h for which the logarithm of the function maximum.

Now let us look at the logarithm of the joint density function.

(Refer Slide Time: 23:30)

(ML)

$$p(\mathbf{y}; h) \equiv \ln p(\bar{\mathbf{y}}; h)$$

$$\ln p(\bar{\mathbf{y}}; h) = \ln \left(\left(\frac{1}{2\pi\sigma^2} \right)^{N/2} e^{-\frac{1}{2\sigma^2} \sum_{k=1}^N (y(k)-h)^2} \right)$$

The logarithm of the [pro] of the likelihood function is basically your law logarithm of 1 over 2 pie Sigma square raise to the power of 2 over 2 e raise - 1 over 2 Sigma square submission K equal to 1 to N y K - h whole square.

And if I take the logarithm of this likelihood function, now can get, you can see

(Refer Slide Time: 24:13)

$$= \ln \left(\left(\frac{1}{2\pi\sigma^2} \right)^{N/2} e^{-\frac{1}{2\sigma^2} \sum_{k=1}^N (y(k)-h)^2} \right)$$

$$= \underbrace{-\frac{N}{2} \ln 2\pi\sigma^2}_{\text{Log Likelihood}} - \frac{1}{2\sigma^2} \sum_{k=1}^N (y(k)-h)^2$$

$\mathcal{L}(\bar{\mathbf{y}}; h) = \ln p(\bar{\mathbf{y}}; h)$
 'Log Likelihood'

- N over 2 ln 2 pie Sigma square - 1 over 2 Sigma square submission K equals 1 to N of y K - h whole square and this is basically the log of the likelihood which is denoted by prescription l y bar parameterised by h. This is basically your log or the natural logarithm ln of p likelihood function p of observation vector y bar parameterised by h.

This is also termed as the log likelihood function. The logarithm of the Likelihood Function, this is also termed as the log, this is also termed as the log likelihood. And instead of maximising the likelihood, I can maximise the log likelihood of the observation vector y bar. And now we can observe something interesting, look at this part in the log likelihood, this is a constant.

So basically this is always a constant, so I did not worry about this. I would not worry about maximizing this, right; if the function is maximum, the function + constant is also a maximum. So I need to maximise this part, but this part has a negative sign, so I need to minimize this part, so I need to look at where I am, I mean this function has a negative sign, so to maximize the log likelihood function; I need to minimize this part.

That is, in order to maximise $-\frac{1}{2} \sum_{k=1}^N (y(k) - h)^2$, I can minimize the rest of the argument and now observe that this factor $\frac{1}{2}$ is a constant, so I am left with is minimising this component which is $\sum_{k=1}^N (y(k) - h)^2$.

So what I am saying is that is equivalent this. Although this log likelihood function might seem complicated to begin with, it is equivalent to basically minimising this part. That is, minimise this part and now that minimisation is easier. I can simply differentiate this and set this equal to 0.

(Refer Slide Time: 26:50)

The image shows a whiteboard with handwritten mathematical derivations. At the top, the equation $\frac{\partial}{\partial h} \sum_{k=1}^N (y(k) - h)^2 = 0$ is written. Below it, the word "minimize." is written in purple, with a green arrow pointing to the equation. Underneath that, the instruction "Differentiate and set equal to zero." is written in green. The next line shows the result of differentiation: $\Rightarrow \sum_{k=1}^N 2(y(k) - h) = 0$. The final line shows the simplified equation: $\Rightarrow \sum_{k=1}^N y(k) = Nh$.

To minimise submission K equal to 1 to N y $K - h$ square. To minimise this, differentiate and set equal to 0 and if I differentiate this, what am I going to get if I differentiate this with respect to h .

I am going to get submission K equal to 1 to N twice y $K - h$ equal to 0 that is differentiating and setting equal to 0 imply submission K equal to 1 twice y $K - h$ equal to 0 which basically implies that submission K equal to 1 to N of y K equal n times h which basically implies that this occurs at your h hat equals, what is the value of h that occurs?

(Refer Slide Time: 28:24)

$$\Rightarrow \sum_{k=1}^N y(k) = Nh$$

$$\Rightarrow \hat{h} = \frac{1}{N} \sum_{k=1}^N y(k)$$

Maximum Likelihood (ML) Estimate of h .

average of observations $y(1), y(2), \dots, y(N)$.

Sample mean

This occurs at value of h equals, this occurs at value of h which is equal to 1 over N submission K equal to 1 to N y of K at this particular value of h is denoted by h hat. This is an estimate of the unknown parameter h that is the value of h at which the Likelihood Function is maximised is basically the estimate of the unknown parameter h .

This is denoted by h hat, this is the Maximum Likelihood Estimate of h . So this is your h hat which we have calculated, this is the maximum likelihood of estimate; this is your Maximum Likelihood Estimate. Let me write this clearly, this is the maximum likelihood or ML estimate of h and one can also denote this by subscript ML to denote that this is the Maximum Likelihood Estimate.

So this h hat is the Maximum Likelihood Estimate and look at this, this is simply the average of the observations, what is this, this is the average, simple average or arithmetic mean of observations. Your observations y_1, y_2 up to y_n . And this is also known as this average is also known as the sample mean. That is the Maximum Likelihood Estimate is given by the

sample mean. What is the sample observation y_1, y_2, \dots, y_N and the mean of this sample is $\frac{1}{N} \sum_{k=1}^N y_k$.

This is the arithmetic mean or the sample mean of the observations and this is very intuitive, what we are saying is the Maximum Likelihood Estimate, they are Maximum Likelihood Estimate of the unknown parameter h is simply to take the average of the observations at the sensor load which is something very intuitive, but we have derived this analytically, rigorously and justified this that is we have formed the likelihood function and this value of h .

This is sample mean of the observations, maximises the likelihood function, therefore this is known as the Maximum Likelihood Estimate.

(Refer Slide Time: 31:05)

$$\Rightarrow h = \frac{1}{N} \sum_{k=1}^N y(k)$$

Maximum Likelihood (ML) Estimate of h .

average of observations $y(1), y(2), \dots, y(N)$.

'Sample mean' \rightarrow ML Estimate

So this sample or turns out that in this case the sample mean is basically your ML, the sample mean is your ML estimate which is something very important which you have learnt in this module.

So what we have started in this module, we have extended our single observation model to a multiple observation or an observation vector model. We found out the joint Probability Density Function of these observations and is the function of the unknown parameter h , we said this is termed as a likelihood.

The value of h at which this likelihood is maximum which corresponds to the maximum likelihood of the parameter h is known as the Maximum Likelihood Estimate. And for this

particular problem we have derived the Maximum Likelihood Estimate as \hat{h} equals $\frac{1}{N} \sum_{k=1}^N y_k$ which is the sample mean.

And this is a very interesting aspect, this is a Maximum Likelihood Estimate which is a very interesting and very important and a very powerful estimation paradigm. This is the Maximum Likelihood Estimation, this example of sensor node making multiple measurements illustrates the the basics, the basics of this Maximum Likelihood Estimation principle.

And in the next module, in further module we will discover, we will explore this Maximum Likelihood Estimate further and discover other properties of this Maximum Likelihood Estimation procedure and the Maximum Likelihood Estimate that we have found. So let us stop here and we will continue in the subsequent model. Thank you very much.
