Channel Estimation across Each Subcarrier in Orthogonal Frequency Division Multiplexing (OFDM)

Hello, welcome to another module in this massive open online course on Estimation Theory for Wireless Communication Systems. And we are looking at OFDM that is Orthogonal Frequency Division Multiplexing. And we said that OFDM very efficiently overcomes the Inter symbol interference in a wireless channel, all right.

(Refer Slide Time: 00:45)

So we are looking at basically OFDM, which is your Orthogonal Frequency... Orthogonal Frequency Division Multiplexing and we are considering, as an example, we are considering a system with N equal to 4 subcarriers and we said that X_0, X_1, X_3 these are the N equal to 4 symbols loaded onto the subcarriers.

(Refer Slide Time: 01:33)

These are basically your N equal to 4 symbols loaded, which are basically loaded onto the, which are loaded onto the subcarriers.

Basically, which means that we are looking at the N equal to 4 point N equal to 4 point IFFT Inverse Fast Fourier Transform of this to generate the samples. So we loading capital X 0, capital X 1, capital X 2, X 3 onto the subcarriers which is, we are taking the N point or 4 point IFFT to generate the samples. And the samples are basically your X 0, X 1, X 2, X 3 where your kth sample.

(Refer Slide Time: 02:33)

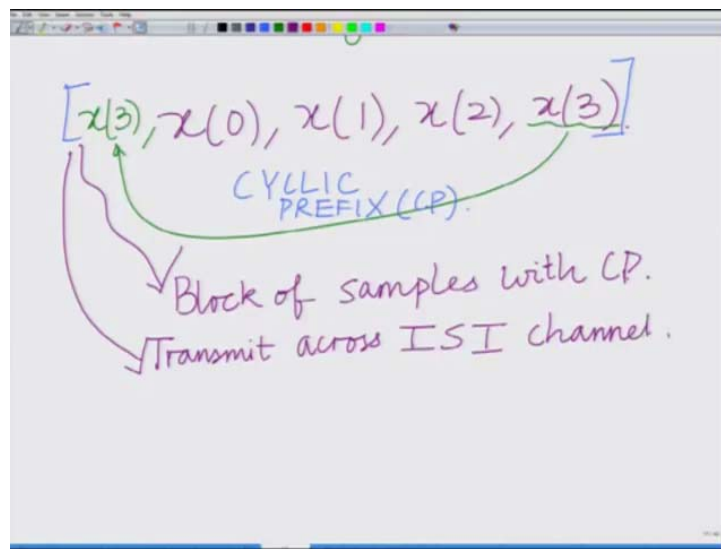

Samples in Time Domain
 $x(k) = \frac{1}{N} \sum_{l=0}^{N-1} X(l) e^{j2\pi \frac{kl}{N}}$
 $= \frac{1}{4} \sum_{l=0}^3 X(l) e^{j2\pi \frac{kl}{4}}$
 $x(k) = \frac{1}{4} \sum_{l=0}^3 X(l) e^{j\frac{\pi}{2} kl}$
kth sample generated by IFFT.

These are the samples in time domain which are actually transmitted over the channel and therefore, basically k th sample x_k equals some L equal to 0 to N minus 1 $x_L e^{j 2 \pi k L / N}$ since this is an IFFT, $e^{j 2 \pi k L / N}$ divided by N . Now substituting N equal to 4, I have N equal to 0 to N minus that is 3 $x_L e^{j 2 \pi k L / 4}$ which means your sample x_k equals $1/4$ summation L equal 0 to 3 $x_L e^{j 2 \pi k L / 4}$.

So this is the k th sample which is generated by the IFFT. So the k th sample generated by the IFFT, correct. And now we have not simply transmitting the samples, we are adding a cyclic prefix that is we are taking some samples from the tail of the block and prefixing them at the head of the block and this is known as the cyclic prefix.

Precisely in this example we have taken one sample, but one can take more also, alright. Or that depends on the length or the number of taps in the channel response, okay.

(Refer Slide Time: 04:30)

So basically, what we are doing is, we have x_0, x_1, x_2, x_3 and what I am doing is basically now I take x_3 and prefix and this is termed as your cyclic prefix or CP are basically the CP.

And now when you take this block with cyclic prefix, this is your block of samples. So the OFDM transmission takes place in blocks. So this is the block of samples with your cyclic prefix and you transmit these across the ISI channel. Transmit this across the Channel with inter symbol interference and what is the channel; we are considering the 2 tap inter symbol interference channel that is y_k equals $h_0 x_k$ plus $h_1 x_{k-1}$ plus v_k .

(Refer Slide Time: 05:54)

$$y(k) = h(0)x(k) + h(1)x(k-1) + v(k).$$

L = 2 Tap ISI channel.

$$y = h \otimes x + v$$

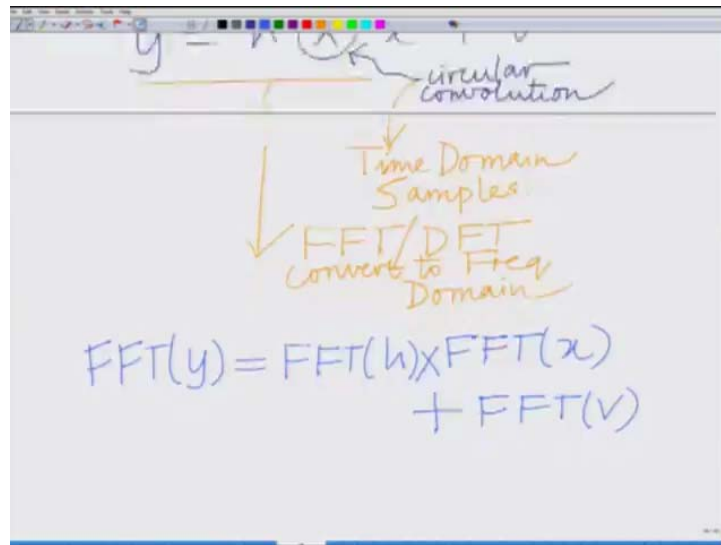

← circular convolution

This is the 2 tap, this is your basically L equal to 2 tap ISI channel. This is your L equal to 2 tap ISI channel. And now when you transmit the samples with the cyclic prefix, that is a cyclic prefix block of samples across this ISI channel, what you get is that the channel action becomes a circular convolution.

So the output basically y is a circular convolution of the channel with the transmitted samples plus the noise and that is what we have also seen yesterday. That is also what we have seen in the previous modules that is, y equals h times x h and where this is basically your circular convolution in a time domain that is, in a domain of the circular convolution.

And it is important to remember that this is the circular convolution in the time domain for the samples.

(Refer Slide Time: 07:05)

Okay, this is the circular convolution and the time domain that is the time domain for the sample. So there is still inter sample interference that is, the inter sample interference is still there, that has not been removed.

However, now once you take the FFT and convert it into a frequency domain. Now you take the whole system, you take the Fast Fourier Transform FFT or basically which is the same thing as your TFT and convert it into the frequency domain. And once you convert it into the frequency domain, what you have is that the circular convolution becomes a multiplication that is, FFT of h times FFT of x plus FFT of your noise.

Let me write this multiplication explicitly. So in the FFT domain, this becomes a multiplication. Multiplication in FFT domain or basically your frequency domain. Let us call this, rather than FFT, probably a better word for this is the frequency or subcarrier domain. Remember, in the frequency we are talking about the various subcarriers in the frequency domain.

(Refer Slide Time: 08:59)

Multiplication in Frequency or Subcarrier Domain

$$Y(l) = H(l) \cdot X(l) + V(l)$$

output symbol across l^{th} subcarrier

Symbol loaded onto l^{th} subcarrier

Channel coefficient for l^{th} subcarrier

The image shows a whiteboard with a handwritten equation $Y(l) = H(l) \cdot X(l) + V(l)$. A pink arrow points from the text 'Multiplication in Frequency or Subcarrier Domain' to the multiplication sign in the equation. A blue arrow points from the text 'output symbol across l^{th} subcarrier' to $Y(l)$. A green arrow points from the text 'Symbol loaded onto l^{th} subcarrier' to $X(l)$. A blue arrow points from the text 'Channel coefficient for l^{th} subcarrier' to $H(l)$.

So in the frequency domain, it is a multiplication which means now basically if you look at the l^{th} subcarrier that is, I have y_L that is in the frequency domain across l^{th} subcarrier is the product h_L times x_L which is the symbol transmitted across the l^{th} subcarrier plus v_L where y_L is the output symbol. Remember, this we said is the output; this is your output symbol across l^{th} subcarrier.

This is your channel coefficient for your l^{th} carrier, okay. This is the symbol loaded onto the l^{th} subcarrier. This is something that we have already seen the capital I . This is the symbol loaded onto the l^{th} , this is the symbol loaded onto the l^{th} subcarrier and v_L is basically the on, this is your noise on the l^{th} subcarrier; this is the noise on the l^{th} subcarrier, so this is the model.

(Refer Slide Time: 10:33)

The image shows a handwritten equation on a whiteboard: $Y(l) = H(l) \cdot X(l) + V(l)$. The equation is annotated with several notes:

- $Y(l)$: output symbol across l^{th} subcarrier
- $H(l)$: Channel coefficient For l^{th} subcarrier
- $X(l)$: Symbol loaded onto l^{th} subcarrier
- $V(l)$: Noise for l^{th} subcarrier

Additional notes include:

- On each subcarrier there is NO ISI.

And therefore what you are saying on the subcarrier, on each subcarrier there is no... And this is important to observe that on each subcarrier there is no ISI. That is there is no Inter Symbol Interference on each subcarrier because y_L equal the coefficient h_L times the symbol x_L on the subcarrier plus V_L . So basically there is no interference Inter Symbol Interference on the symbol x_L capital x_L which is basically the symbol loaded onto the subcarrier.

Therefore, it very efficiently removes ISI using simply the IFFT at the transmitter and the FFT operation at the receiver. And now since we have N equal to 4 subcarriers, we may simply expressively write it down so that we can formulate the system model, then see how the estimation of this of this channel coefficient can be done. And that is indeed going to be very simple. So if I write the system for the N equal to 4 subcarriers.

(Refer Slide Time: 11:53)

$$N = 4 \text{ subcarriers.}$$
$$l = 0, 1, 2, 3.$$
$$\begin{cases} Y(0) = X(0)H(0) + V(0) \\ Y(1) = X(1)H(1) + V(1) \\ Y(2) = X(2)H(2) + V(2) \\ Y(3) = X(3)H(3) + V(3) \end{cases}$$

→ $N = 4$ subcarriers:

So remember we said we have N equal to 4 subcarriers are responding to l equal to 0, 1, 2, 3 which means across subcarrier 0 I have y_0 equals $x_0 h_0$ just writing $h x$ as $x h$ because this is convenient. y_1 equals $x_1 h_1$ plus V_1 by the same token, again this is very simple, something that you can already guess y_2 equals $x_2 h_2$ plus V_2 and y_3 equals $x_3 h_3$ plus V_3 , this is across your...

N equal to 4, this is across your N equal to 4 this is across your N equal to 4 subcarriers. And now I can write this as a matrix, so basically what I can do now is I can basically make a vector out of this, I can use it, I can model it, I can represent it using vector notation. That is what we have done many times before and it is going to be very simple. Now if I write it as a vector, now we can clearly see, write it is as a vector.

(Refer Slide Time: 13:35)

The diagram shows the frequency domain representation of an OFDM system. At the top, it states $Y(3) = X(3)H(3) + V(3)$ and notes $N = 4$ subcarriers. Below this, a vector equation is presented:
$$\begin{bmatrix} Y(0) \\ Y(1) \\ Y(2) \\ Y(3) \end{bmatrix} = \begin{bmatrix} X(0) & 0 & 0 & 0 \\ 0 & X(1) & 0 & 0 \\ 0 & 0 & X(2) & 0 \\ 0 & 0 & 0 & X(3) \end{bmatrix} \begin{bmatrix} H(0) \\ H(1) \\ H(2) \\ H(3) \end{bmatrix} + \begin{bmatrix} V(0) \\ V(1) \\ V(2) \\ V(3) \end{bmatrix}$$
 The matrix X is labeled as the "Diagonal Matrix". The vector H is labeled as the "Frequency Domain" channel coefficients. The vector V represents the noise across each subcarrier.

That is, I have y_0, y_1, y_2, y_3 , let me call this vector \bar{y} . You can see this is basically this diagonal matrix of x_0, x_1, x_2, x_3 , this is basically.

Let us call this matrix x which is your diagonal matrix, times the matrix of channel coefficients h_0 or the vector of channel coefficient across each subcarrier rather h_2, h_3 plus again the noise vector it is the noise across each sub carrier capital V_0, V_1, V_3 , so this is your channel vector, this is your noise vector.

And remember, this whole model is basically in the frequency domain because we are writing it across each subcarrier. This whole model represents the frequency domain representation of this OFDM system. That is y_L equals x_L the symbol loaded onto the subcarrier times h_l , the channel coefficient across subcarrier plus capital V_l , which is the noise sample on subcarrier l .

(Refer Slide Time: 15:30)

The diagram shows the equation $\bar{Y} = X \bar{H} + \bar{V}$ written in blue ink on a whiteboard. The equation is annotated with green arrows pointing to each term. Below the equation, the following dimensions and domain labels are written in red and purple ink:

- \bar{Y} : $N \times 1$ Pilot output Subcarrier Domain
- X : $N \times N$ 4×4 Pilot Matrix in Subcarrier Domain
- \bar{H} : $N \times 1$ 4×1 Channel vector
- \bar{V} : $N \times 1$ 4×1 Noise vector

At the top of the whiteboard, the words "Diagonal matrix" and "Frequency Domain" are written in purple ink.

And now we have converted into matrix model where \bar{y} equals x times \bar{h} plus \bar{V} where x equals, you can see this is an N cross N that is in, this case 4 cross 4 diagonal matrix. \bar{Y} bar this is N cross 1 vector, \bar{h} bar is your N cross 1 that is again 4 cross 1 coefficient vector. And \bar{V} bar is basically your N cross 1 or basically your 4 cross 1 noise vector.

This is an equivalent channel vector, you can think of this as basically your channel vector in the frequency domain and you can think of this as the pilot matrix in the subcarrier domain. That is, the diagonal matrix x if we are transmitting pilot symbols on to the [sum] subcarrier, so this is the pilot matrix in the subcarrier domain. That is where, and this is the receive pilot outputs in the subcarrier domain.

For channel estimation, these are the pilot outputs in the subcarrier domain. Basically what we are saying is, we are considering capital X_0 , capital X_1 , capital X_2 , capital X_3 to be the N pilots loading onto the N subcarrier. So basically what we are saying is we have 4 purposes of channel estimation, if we load the pilots onto the subcarriers, so these are your pilots loaded onto the subcarriers.

(Refer Slide Time: 17:27)

$$[X(0), X(1), X(2), X(3)]$$

Pilots loaded onto subcarriers.

$$\bar{Y} = X \bar{H} + \bar{V}$$

Pilot Matrix

These are the pilots which are loaded onto the subcarriers and therefore what I have is, now I have a familiar y equals x h bar plus V bar where this is the pilot matrix. This is something what we have seen many times before, even in the downlink channel estimation where we have the receive vector basically y equals pilot matrix x times the channel vector h plus the noise vector.

And therefore now, one can formulate the channel estimation problem that is, the estimation of the coefficient vector capital H bar as a Least Squares problem. So naturally I can now formulate this as a Least squares problem and it is going to be a Least squares problem. So channel estimation, I'm going to formulate this as a Least squares problem. This is going to be your Least Squares that is LS problem for channel estimation.

(Refer Slide Time: 18:42)

Pilot Matrix
For channel Estimation
Least Squares (LS)
Problem.

$$\min_{\bar{H}} \|\tilde{Y} - X \bar{H}\|^2$$

complex matrix X

$$\hat{H} = (X^H X)^{-1} X^H Y.$$

Which is simply now like many times before, y minus h x bar square and we would like to minimise it with respect to h bar that is, we would like to find the h bar which minimises this Least Squares function and that gave the Maximum Likelihood Estimate and remember that is also something that we had derived and the least squares solution again is very simple.

That is, h hat equal x hermitian considering complex symbols. X hermitian that is simply replacing the transposed by hermitian x hermitian x inverse x hermitian y that is basically... Remember, previously we had x transpose x inverse x transpose. Why I am simply replacing the transpose by hermitian, because of to allow complex matrix x , yeah. And therefore what we have and now therefore now let me write this again a little bit clearly.

(Refer Slide Time: 19:56)

$$\hat{H} = (X^H X)^{-1} X^H Y.$$

$$\hat{H} = (X^H X)^{-1} X^H Y$$

LS Estimate
of coefficient vector

$x^H x^{-1} x^H y$, this is the Least Square estimate of the coefficient vector. This is the Least Square or the LS estimate of the coefficient vector, right. $x^H x^{-1} x^H y$ right, where y basically vector y is the FFT of the outputs received of the sample, output samples received in the time domain.

Basically, \bar{y} is the vector of outputs across the various subcarriers, correct. And x is basically the diagonal matrix consisting of the pilot symbols which are loaded onto the subcarriers and now if you observe something interesting, this matrix x is a diagonal matrix which is basically invertible, right.

So if you look at this is slightly different from the Least Square that we have seen before, your x is a x basically equals. In fact, let me just write it expressively.

(Refer Slide Time: 21:15)

The diagram shows a handwritten equation: $X = N \begin{bmatrix} x(0) & 0 & 0 & 0 \\ 0 & x(1) & 0 & 0 \\ 0 & 0 & x(2) & 0 \\ 0 & 0 & 0 & x(3) \end{bmatrix}$. The matrix is labeled as an $N \times N$ matrix and is described as a "Diagonal Matrix Invertible matrix". A note above the matrix says "of coefficient vector".

This is your x_0, x_1, x_2, x_3 which is an only diagonal entries are nonzero, rest of the entries are 0. So basically your x is a diagonal matrix.

X is a diagonal matrix which is invertible and therefore what you have, so this matrix is basically this is an invertible matrix. This is basically an invertible matrix which means now what you have is normally, see remember previously we said, so this is an N cross N matrix, so X is basically a square.

In fact, diagonal matrix and hence x is invertible. Previously, when we considered the pilot matrix, remember the pilot matrix we said is N cross M where N is a number of pilot vectors

and [a] M is basically the number of antennas at the base station. That was in the case of multi-antenna downlink channel estimation.

Here we have something very interesting because of the nature of OFDM channel estimation. We have, if the pilot matrix x is N cross N , it is a square matrix. So therefore in fact it is invertible and hence in this scenario particularly, x hermitian x , since x is a invertible matrix, this is not always true, so this becomes x inverse times x hermitian inverse.

(Refer Slide Time: 22:46)

The image shows a whiteboard with handwritten mathematical derivations. At the top, it says "N x N. Invertible matrix". Below that, the equation $(X^H X)^{-1} = X^{-1} (X^H)^{-1}$ is written in pink. A green arrow points from this equation to the next one, with the note "Because in OFDM X is N x N, invertible." Below that, the channel estimate equation is derived: $\hat{H} = (X^H X)^{-1} X^H \bar{Y}$ and $= X^{-1} (X^H)^{-1} X^H \bar{Y}$.

This is only for this scenario because x is invertible. This is not because $x X$ is invertible, this is not generally true, and this is only true in this scenario because in OFDM and this OFDM scenario X is N cross N . It is an N cross N invertible matrix. And therefore now if I substitute this, I have \hat{h} equals x hermitian x inverse x hermitian y bar which is basically now x inverse into x hermitian inverse into x hermitian into y bar.

Of course you can see x hermitian inverse into x hermitian, this is identity, so this is simply now very interestingly simply x inverse y bar where x is basically your, where x is basically, this x is basically your pilot matrix pilot matrix.

(Refer Slide Time: 24:15)

$\hat{H} = X^{-1} \bar{Y}$

Pilot matrix

Since X is DIAGONAL
 X^{-1} is easy to compute

$$X^{-1} = \begin{bmatrix} \frac{1}{X(0)} & 0 & 0 & 0 \\ 0 & \frac{1}{X(1)} & 0 & 0 \\ 0 & 0 & \frac{1}{X(2)} & 0 \\ 0 & 0 & 0 & \frac{1}{X(3)} \end{bmatrix}$$

And also since the pilot matrix is diagonal, since it is a diagonal matrix, x inverse is also very easy to compute.

If basically the inverse of each of the diagonal elements that is the reciprocal of each of the diagonal elements. Therefore, x inverse simply, since x is a diagonal matrix, this is also important to note. Since x is diagonal, x inverse is easy to compute. When I say easy, it means it is sufficient, x inverse is simply basically your 1 over x_0 , 1 over x_1 , 1 over x_2 , the rest are 0s.

This is your diagonal matrix and therefore now if I look at h hat.

(Refer Slide Time: 25:28)

$$\begin{bmatrix} \hat{H}(0) \\ \hat{H}(1) \\ \hat{H}(2) \\ \hat{H}(3) \end{bmatrix} = \begin{bmatrix} \frac{1}{X(0)} & 0 & 0 & 0 \\ 0 & \frac{1}{X(1)} & 0 & 0 \\ 0 & 0 & \frac{1}{X(2)} & 0 \\ 0 & 0 & 0 & \frac{1}{X(3)} \end{bmatrix} \begin{bmatrix} Y(0) \\ Y(1) \\ Y(2) \\ Y(3) \end{bmatrix}$$
$$\hat{H}(0) = \frac{Y(0)}{X(0)}$$
$$\hat{H}(1) = \frac{Y(1)}{X(1)}$$
$$\hat{H}(2) = \frac{Y(2)}{X(2)}$$

Estimate of the vector \hat{h} that is estimate of h_0, h_1, h_2, h_3 , this is simply x inverse that is $1/x_0, 1/x_1, 1/x_2, 1/x_3$ times the symbol vector received across the subcarriers, that is y which is y_0, y_1, y_2, y_3 and now therefore now since this is diagonal matrix.

Now if you look at this, you have $1/x_0$ multiplying by y_0 , you have $1/x_1$ multiplying y_1 , you have $1/x_2$ multiplying y_2 , x_3 multiplying y_3 . Now therefore the channel estimates are very simple, it is simply \hat{h}_0 equals y_0 divided by x_0 , \hat{h}_1 is basically your y_1 divided by x_1 , \hat{h}_2 equals y_2 divided by x_2 and finally \hat{h}_3 equals y_3 divided by x_3 .

(Refer Slide Time: 27:13)

Handwritten whiteboard notes showing the formula for channel estimation:

$$\hat{H}(l) = \frac{Y(l)}{X(l)}$$

Annotations:

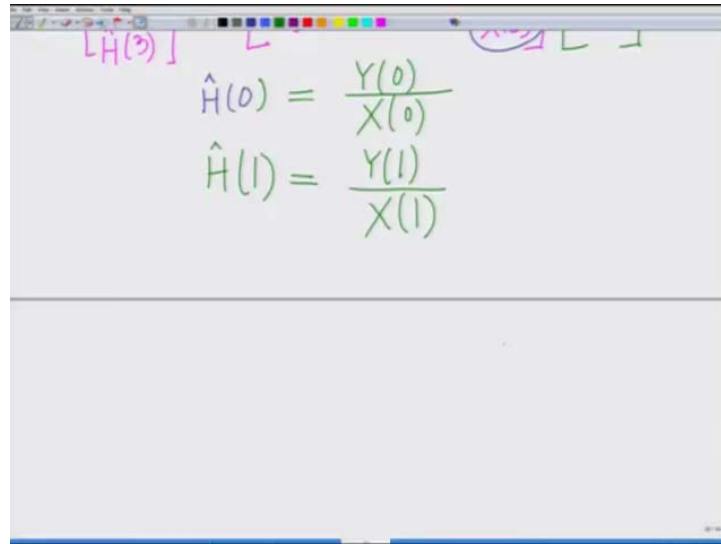

- $Y(l)$: pilot output across subcarrier l .
- $X(l)$: pilot symbol across subcarrier l .
- $\hat{H}(l)$: estimate of coefficient across subcarrier l .

That is basically the estimate of the channel coefficient across each subcarriers N is simply the pilot output across the subcarrier divided by the pilot input across the subcarrier and that is very simple to see. So basically summarising this channel estimates, \hat{h}_k equals y_k divided by x_k , this is what, this is the estimate of coefficient or let us write it in terms of l , since that is the notation that we are using.

\hat{h}_L equals y_L divided estimate of coefficient across subcarrier l , y_L symbol across subcarrier l . The pilot output symbol, pilot output across subcarrier L and x_L is basically your pilot symbol. This is basically the pilot symbol across subcarrier L and therefore, if we look at this across each subcarrier, we have \hat{h}_l .

It is very simple, the estimate of coefficient across subcarrier N is simply y_L divided by x_L where x_L is the pilot symbol loaded onto the L th subcarrier, all right. So the estimate \hat{h}_0 is equal to, you can clearly see.

(Refer Slide Time: 29:04)

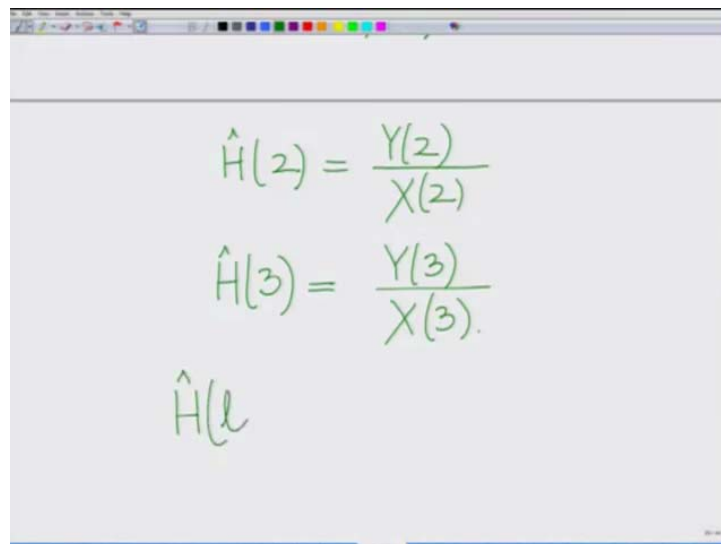

A screenshot of a whiteboard showing handwritten equations for channel estimates. The equations are:

$$\hat{H}(0) = \frac{Y(0)}{X(0)}$$
$$\hat{H}(1) = \frac{Y(1)}{X(1)}$$

This is y_0 divided by x_0 , \hat{h}_1 equals y_1 divided by x_1 .

(Refer Slide Time: 29:20)

A screenshot of a whiteboard showing handwritten equations for channel estimates. The equations are:

$$\hat{H}(2) = \frac{Y(2)}{X(2)}$$
$$\hat{H}(3) = \frac{Y(3)}{X(3)}$$

Below these, the general formula is written as:

$$\hat{H}(L)$$

\hat{h}_2 similarly equals y_2 divided by x_2 and \hat{h}_3 this is equal to y_3 divided by x_3 . And in general therefore one can say the estimate of the coefficient on the L th subcarrier \hat{h}_L equals y_L divided by x_L .

(Refer Slide Time: 29:52)

A handwritten equation on a whiteboard: $\hat{H}(l) = \frac{Y(l)}{X(l)}$. The equation is enclosed in a hand-drawn orange box. Above the box, the text $X(0)$ is written in green. Below the box, an arrow points from the text "Estimate of Coefficient on lth Subcarrier." to the $\hat{H}(l)$ term.

This is what is $\hat{H}(l)$, l is basically, this is the estimate of the coefficient on the l th subcarrier. This is the estimate, this is the estimate of the coefficient on the l th subcarrier, all right.

So we are saying $\hat{H}(l)$ equals $y(l)$, that is the received pilot symbol $y(l)$ on the l th subcarrier divided by $x(l)$ which is the transmitted pilot symbol on the l th subcarrier. And therefore now if I look at this, now if I look at the coefficient $\hat{H}(0)$, $\hat{H}(1)$, now remember what we said earlier, remember.

(Refer Slide Time: 30:55)

A handwritten diagram on a whiteboard. At the top, a green vector is written: $[h(0), h(1), 0, 0]$. To its left, the text "Channel Taps" is written in blue with an arrow pointing to the vector. Below this vector, a green arrow points down to a red vector: $[H(0), H(1), H(2), H(3)]$. To the right of the green arrow, the text $N=4$ is written in red, with "FFT or DFT" written below it. To the left of the red vector, the text "Coefficients of Subcarriers" is written in blue with an arrow pointing to the vector.

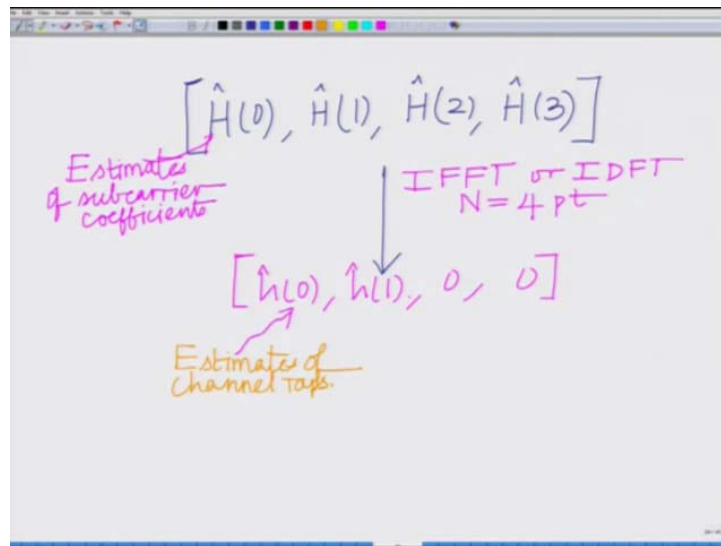

The \hat{h} , the capital H, what are they, they are given by the FFT of the channel taps, remember we had $[h_0, h_1, 0, 0]$ and you look at the $N=4$ point IFFT or $N=4$ point FFT or basically your DFT, you get the capital H S which are basically the channel coefficients corresponding to the subcarriers, right.

These are the coefficients for the subcarriers, so what are these, these are your channel taps and these are the coefficients corresponding to the various coefficients of the subcarrier. So the coefficients of the subcarrier, channel coefficients of the subcarriers are given by the 0 padded FFT of the channel taps. But therefore, from the estimates of the coefficients of the subcarriers, if you want to construct the channel taps, we have to look at the IFFT.

Right, because the channel taps FFT use the channel coefficients of the subcarriers, the coefficients on the subcarriers, if you take the IFFT or the IDFT, you get back the taps. So now we have the estimates of the channel coefficient on the subcarrier. How do we find the channel taps, estimates of the channel taps, we take the IFFT or IDFT.

And therefore naturally what we want to do is...

(Refer Slide Time: 32:38)

I have $\hat{h}(0)$, $\hat{h}(1)$, $\hat{h}(2)$, $\hat{h}(3)$ and what do I do, I basically take the IFFT or basically IDFT. $N=4$ point... To get back your $\hat{h}(0)$, to get back the estimates of the, what are these, these are the basically your estimates of the channel taps. So these are the estimates of the so these are estimates of the subcarrier coefficients. These are the estimates of your channel taps.

(Refer Slide Time: 34:01)

Handwritten notes on a whiteboard. At the top, the word "Coefficients" is written in pink. Below it, a vector is written in pink: $[\hat{h}(0), \hat{h}(1), 0, 0]$. An arrow points from this vector to the text "Estimate of channel taps" written in orange. Below this, the general formula for the estimate of the kth channel tap is written in green: $\hat{h}(k) = \frac{1}{N} \sum_{l=0}^{N-1} \hat{H}(l) e^{j2\pi \frac{kl}{N}}$. Below the formula, the text "Substitute N = 4" is written in orange.

In other words, basically what we are saying is this $\hat{h}(k)$ which is the estimate of the channel tap of the subcarrier k or the estimate of the k th channel tap is given by the N point IFFT, that is $\frac{1}{N}$, L equal to 0 to N minus 1 , $\hat{H}(l)$, $e^{j2\pi \frac{kl}{N}}$ and now here, I am going to substitute an equal to 4 . Now substitute N equal to 4 .

(Refer Slide Time: 35:08)

Handwritten notes on a whiteboard. At the top, the text "Substitute N = 4" is written in orange. Below it, the formula is written in orange: $\hat{h}(k) = \frac{1}{4} \sum_{l=0}^3 \hat{H}(l) e^{j2\pi \frac{kl}{4}}$. Below this, the same formula is written in green and enclosed in a green box: $\hat{h}(k) = \frac{1}{4} \sum_{l=0}^3 \hat{H}(l) e^{j\frac{\pi}{2} kl}$. An arrow points from this boxed formula to the text "Estimate of kth channel tap." written in green.

Which means what I have is $\hat{h}(k)$ equals $\frac{1}{4}$ L equal to 0 to 3 , $\hat{H}(l)$ $e^{j2\pi \frac{kl}{4}}$ divided by 4 which is basically $\frac{1}{4}$ L equal to 0 to 3 $\hat{H}(l)$ $e^{j\frac{\pi}{2} kl}$. This is the expression for the estimate of the k th; this is estimate for the expression of the k th channel tap. So this is the estimate of the k th channel tap.

Expression for the estimate of the kth channel tap which is given by the IFFT of the estimates of the subcarrier coefficients that is, estimates of the channel coefficients of the various subcarriers. And the [IF] size of the IFFT or the IDFT is N equal to 4 point. Okay, for example, h hat 0, if you look at h hat of 0, I now have to do is, I have to substitute basically your k equal to 0 corresponds to k equal to 0.

(Refer Slide Time: 36:25)

The image shows handwritten mathematical derivations for channel tap estimation. The first part shows the estimate of the 0th tap, $\hat{h}(0)$, which is equal to $\frac{1}{4} \sum_{l=0}^3 \hat{H}(l) e^{j\frac{\pi}{2} \cdot 0 \cdot l}$. This simplifies to $\frac{1}{4} \sum_{l=0}^3 \hat{H}(l)$. The second part shows the estimate of the 1st tap, $\hat{h}(1)$, which is equal to $\frac{1}{4} \sum_{l=0}^3 \hat{H}(l) e^{j\frac{\pi}{2} \cdot 1 \cdot l}$. This simplifies to $\frac{1}{4} \sum_{l=0}^3 \hat{H}(l) e^{j\frac{\pi}{2} l}$.

So this is 1 over 4, submission L equal to 0 to 3, h hat L, e power j pie by 2, k equal to 0 0 tads L, so this quantity is 1, so this is basically 1 over 4 submission L equal to 0 to 3, h hat of L, e power, well this thing is one, so it is simply submission 1 over 4 L equal to 0 to 3 h hat of L and h hat of 1 which is the estimate of the first channel tap is 1 over 4, basically that corresponds to k equal to 1, L equal to 0 to 3, h hat of L, e power j pie by 2, k equal to 1 into L.

So this is basically 1 over 4, L equal to 0, h hat of L, e power j pie by 2 into L. So this is estimate of channel tap 0 or estimate of 0 (()) (37:48) and this is basically your estimate of the first tap. This is basically the estimate of the first tap.

This is estimate of the channel tap 1, okay. So basically what we have over here, now what we have done, we have comprehensively demonstrated how to do channel estimation for an OFDM that is Orthogonal Frequency Division Multiplexing System.

So in this module and the past modules, what we have seen is first we have formulated, we have developed the model for OFDM or Orthogonal Frequency Division Multiplexing based transmission where we said we have symbols which are loaded into the subcarriers that is,

basically perform the IDFT followed by the cyclic prefix, transmit them over the frequency select or the Internet symbol interference channel, right.

At the receiver perform the FFT, that converts, that basically because of the cyclic prefix action of the channel is that of circular convolution, so basically in the FFT domain the action of the channel is that of multiplication, the channel coefficient is multiplied across each subcarrier with the transmitted symbol plus of course you have additive noise.

And then we formulated, considering these symbols loaded onto the subcarrier to be pilot symbols, we formulated the least squares channel estimation problem, we estimated the channel coefficients corresponding to the various subcarriers.

In fact, we said that it is very simple, what we have to do is we have to take the received pilot symbol capital Y_L across subcarrier L divided by the transmitted pilot symbol capital X_L on the L th subcarrier, that is capital Y_L divided by X_L that gives capital \hat{h}_L . The estimates of the channel coefficient across subcarrier L remember, this is the channel coefficient in the frequency domain.

Now to get the time domain channel coefficients, what paved we have to do is we have to take the IFFT similarly, the N equal to 4 point IFFT and then you get the corresponding estimates of the channel taps in the time domain. So that is how, that is how enquiry or in summary how OFDM channel estimation works, alright.

So we will stop this module here, in the subsequent module we will look at a simple example, because examples illustrate things clearly, so we will look at element example to see how this whole mechanism of OFDM channel estimation works, alright so we will stop this module. Thank you very much.
