Sequential Estimation of Wireless Channel Coefficient - Estimate and Variance Update Equations

Hello, welcome to another module in this massive open online course on Estimation for Wireless Communications. So we are currently looking at sequential estimation in which we are continuously updating the estimate at every time instant and we are looking at it in the context of wireless channel estimation, correct. So we are looking at sequential estimation, where we are continuously updating the estimate.

(Refer Slide Time: 00:38)

We are continuously updating, not recomputing, we are updating the estimate at every time instant N or at each time instant N , correct. So we are computing the estimate \hat{h}_N at time instant N , \hat{h}_{N+1} at time instant $N+1$, \hat{h}_{N+2} at time instant $N+2$ and so on. And the important thing to realise here is that we are not recomputing the estimate at every time instant.

But using the previous that is the latest estimate that is available and simply updating it at every time instant, okay. That is important as we have said in several practical applications because we cannot recompute the estimate at every time instant, right. And we are looking at

this in the context of wireless channel; we are looking at sequential estimation in the context of our wireless channel estimation problem.

Where we have y_k the received symbol equals h times $x_k + v_k$. And this h is the fading Channel coefficient which has to be estimated, this is your unknown fading Channel this is your unknown fading Channel coefficient which has to be estimated and we are considering that transmission of pilot symbols. Remember, we said x_k , this is your pilot symbol.

We are considering the transmission of N pilot symbols that is capital N pilot symbols.

(Refer Slide Time: 03:20)

Consider the transmission of N pilot symbols \bar{x}

$$\begin{bmatrix} y(1) \\ y(2) \\ \vdots \\ y(N) \end{bmatrix} = \begin{bmatrix} x(1) \\ x(2) \\ \vdots \\ x(N) \end{bmatrix} h + \begin{bmatrix} v(1) \\ v(2) \\ \vdots \\ v(N) \end{bmatrix}$$

Labels in the diagram:
 - Fading channel coefficient: h
 - Pilot Symbol: \bar{x}

Consider the transmission of N pilot symbols and for this N pilot symbols remember, we said power output symbols y_1, y_2 up to y_N can be represented as the vector \bar{y} equals your pilot vector that is x_1 , this is the N dimensional pilot vector x_1, x_2 up to x_N .

This is your pilot vector which is \bar{x} times of course the fading Channel coefficient $h +$ your noise vector v_1 consisting of noise samples v_1, v_2 up to v_N , this is your noise vector \bar{v} , as a result we have the vector model which is $\bar{y} = \bar{x} h + \bar{v}$.

(Refer Slide Time: 04:23)

$$\bar{y} = \bar{x}h + \bar{v}$$

\bar{y} : N x 1 output vector
 \bar{x} : Pilot vector
 \bar{v} : Noise vector

$$\hat{h}(N) = \frac{\bar{x}^T \bar{y}}{\bar{x}^T \bar{x}} = \frac{\sum_{k=1}^N x(k)y(k)}{\sum_{k=1}^N x^2(k)}$$

This is your N dimensional output vector to, correct. Y bar is your N cross 1; this is your N cross 1 output vector.

This is the N cross 1 pilot vector, h is the fading Channel coefficient and v bar is your noise vector also your N dimensional noise vector, correct. And now we know that remember we have to compute, we compute the estimate, this is the estimate at time instant N because we have received N pilot symbols x 1, x 2 up to x N and we can compute the estimate h hat of N at time instant N as we already know.

That is h hat of N equals x bar transpose y bar divided by x bar transpose x bar, which is equal to basically your submission k equal to 1 to N that is x k y k divided by submission k equal to 1 to N x square of k. This is h hat of N, this is the estimate at time instant N, this is the estimate at time instant N corresponding to N received pilot symbols and also the variance p of N at time instant remember, this is Sigma Square.

(Refer Slide Time: 06:27)

$$P(N) = \frac{\sigma^2}{\|\bar{x}\|^2} = \frac{\sigma^2}{\sum_{k=1}^N x^2(k)}$$

variance of estimate at time N.

Consider now pilot symbol $x(N+1)$ and output symbol $y(N+1)$.

$$y(N+1) = h x(N+1) + v(N+1)$$

We already derived the expression for it divided by norm \bar{x} square σ^2 divided by norm \bar{x} square which is σ^2 divided by summation k equal to 1 to N x^2 of k . And what is p of N ; this is the variance of the estimate that is variance of the estimate or variance of variance of the estimation error basically, we can think of this as the variance of the estimation error or basically, the mean square error.

This is your variance of estimate at time and basically this is also the mean square error at time N okay. Now what we said is we have a new pilot symbol transmitted small x of $N - 1$ at time instant N small x of $N + 1$ at time instant $N + 1$ and corresponding to that we have the observed output symbol small y of $N + 1$ at time $N + 1$.

You want to use this new information to update the channel estimate \hat{h} of N at time instant N to \hat{h} of $N + 1$ at time instant $N + 1$ okay. So naturally what we have now, consider now the pilot symbol x_{N+1} and output symbol y_{N+1} and corresponding to that we have y_{N+1} equals h times x_{N+1} + v_{N+1} okay, this is at time instant $N + 1$ and therefore the estimate \hat{h}_N at time instant $N + 1$.

One way to compute the estimate at time instant $N + 1$ look at this, I can simply replace this N , one simple way to simply replace this N by $N + 1$.

(Refer Slide Time: 08:44)

The slide shows the least squares estimate $\hat{h}(N)$ and its variance $P(N)$ at time instant N . The estimate is given by $\hat{h}(N) = \frac{\bar{x}^T y}{\bar{x}^T \bar{x}} = \frac{\sum_{k=1}^N x(k)y(k)}{\sum_{k=1}^N x^2(k)}$. The variance is given by $P(N) = \frac{\sigma^2}{\|\bar{x}\|^2} = \frac{\sigma^2}{\sum_{k=1}^N x^2(k)}$. The slide also includes labels for 'output vector', 'input vector', and 'variance of estimate at time N'.

And therefore now I have to recompute the estimate, all I have to do is I have k equal to 1 to $N + 1$ $x(k)y(k)$ divided by submission k equal to 1 to $N + 1$ $x^2(k)$ okay, so this is your estimate.

(Refer Slide Time: 09:12)

The slide shows the recomputation of the estimate at time $N+1$. The estimate is given by $\hat{h}(N+1) = \frac{\sum_{k=1}^{N+1} x(k)y(k)}{\sum_{k=1}^{N+1} x^2(k)}$. The slide also includes labels for 'Estimate at time N+1' and 'Recomputing Estimate'.

However, remember what we said this is basically recomputing the, this is simply recomputing the estimate, all right. We are not using the previous estimate $\hat{h}(N)$ and the variance $P(N)$ right. We do not want to do it because recomputing the estimate is simply increases the complexity at every time instant physically, you are again starting from the beginning and you are recomputing.

Basically, starting from scratch and recomputing the entire estimate and that is what we do not want to do, we want to simply update the estimate and that is the procedure that we are going to describe next. So now observe that, I can write this estimate at time instant $N + 1$ as follows. I can write this as submission k equal to 1 to N $x_k y_k + x_{N+1} y_{N+1}$.

That is separating the contribution of the term $N + 1$ divided by submission k equal to 1 to N of $x_k^2 +$ again x_{N+1}^2 . By the way this is the estimate at time instant $N + 1$, \hat{h} hat of $N + 1$ lest we not forget this is the estimate at time instant $N + 1$. And I am writing this as submission k equal to 1 to N $x_k y_k + x_{N+1} y_{N+1}$ divided by submission k equal to 1 to N $x_k^2 + x_{N+1}^2$.

And now if you observe this term over here that a submission k equal to 1 to N $x_k y_k$ look at this.

(Refer Slide Time: 11:24)

The image shows a whiteboard with handwritten mathematical derivations. At the top, three labels are written in pink: "N x 1 output vector" with an arrow pointing to the numerator of the first equation, "Pilot vector" with an arrow pointing to the denominator, and "Noise vector" with an arrow pointing to the noise term in the second equation. The first equation is $\hat{h}(N) = \frac{\bar{x}^T y}{\bar{x}^T \bar{x}}$. Below it, a note says "Estimate at time instant N." The second equation is $\hat{h}(N) \sum_{k=1}^N x^2(k) = \sum_{k=1}^N x(k)y(k)$. The third equation is $P(N) = \frac{\sigma^2}{\|\bar{x}\|^2} = \frac{\sigma^2}{\sum_{k=1}^N x^2(k)}$. A red arrow points to the $P(N)$ term.

This is something that we already have that is submission k equal to 1 to N $x_k y_k$, that is equal to so we have from this relation if you observe what we have here is basically \hat{h} hat of N times submission k equal to 1 to N x_k^2 is basically your submission k equal to 1 to N $x_k y_k$ and this is what I am going to substitute over below.

That is submission k equal to 1 $x_k y_k$ equals \hat{h} hat N into submission k equal to 1 to N x_k^2 , so substituting that what I have over here is basically.

(Refer Slide Time: 12:05)

$$\begin{aligned}
 & \sum_{k=1}^N x^2(k) + x^2(N+1). \\
 = & \frac{\hat{h}(N) \sum_{k=1}^N x^2(k) + x(N+1)y(N+1)}{\sum_{k=1}^N x^2(k) + x^2(N+1)}. \\
 = & \frac{\hat{h}(N) \left(\sum_{k=1}^N x^2(k) + x^2(N+1) - x^2(N+1) \right) + x(N+1)y(N+1)}{\sum_{k=1}^N x^2(k) + x^2(N+1)}.
 \end{aligned}$$

This quantity here is your \hat{h} of N times submission k equal to 1 to N x square of k + the rest stays as it is, $x(N+1), y(N+1)$ divided by k equals 1 to N x square of k + x square of $N+1$. And now what I am going to do is from this factor over here.

I am going to add and subtract x square of $N+1$, so that basically you can see what I am going to do now, it is very simple, it is not complicated at all. I am going to simply write this as \hat{h} of N times well, submission k equal to 1 to N x square of k + x square of $N+1$ - x square of $N+1$ that is basically adding and subtracting x square of $N+1$ and the rest remains as it is.

That is $x(N+1)$ times $y(N+1)$ divided by submission k equal to 1 to N x square of k + x square of $N+1$ that remains the same and now if you look at this, if you look at this part over here, can see that this part is that submission x square of k + x square of $N+1$ is same as the denominator, so that cancels and what we have is now if you simplify it a little patiently, what you have is \hat{h} of $N+1$ now I am going to write the rest of the term.

(Refer Slide Time: 14:22)

$$\begin{aligned}
 &= \frac{\hat{h}(N) \cdot \left(\sum_{k=1}^N x^2(k) + x^2(N+1) \right)}{\sum_{k=1}^N x^2(k) + x^2(N+1)} \cdot y(N+1) \\
 &= \hat{h}(N) + \frac{-x^2(N+1) \hat{h}(N) + x(N+1)y(N+1)}{\sum_{k=1}^N x^2(k) + x^2(N+1)} \\
 &= \hat{h}(N) + \frac{x(N+1)}{\sum_{k=1}^N x^2(k) + x^2(N+1)} \cdot \underbrace{(y(N+1) - \hat{h}(N)x(N+1))}_{e(N+1)}
 \end{aligned}$$

That is, $-x^2(N+1)$ into $\hat{h}(N) + x(N+1)y(N+1)$ divided by $\sum_{k=1}^N x^2(k) + x^2(N+1)$ equal to $\hat{h}(N) + \frac{-x^2(N+1)\hat{h}(N) + x(N+1)y(N+1)}{\sum_{k=1}^N x^2(k) + x^2(N+1)}$, okay. So now we have simplified that and now I am going to simplify it more, just write it in particular, so I have $\hat{h}(N)$ remember that is the, so now if you look at this, now I have already $\hat{h}(N)$, this is the estimated time instant $N+1$ can take $x(N+1)$ common.

So I have $x(N+1)$ divided by $\sum_{k=1}^N x^2(k) + x^2(N+1)$ times $(y(N+1) - \hat{h}(N)x(N+1))$. Now look at this, I can write this as $y(N+1) - \hat{h}(N)x(N+1)$. And therefore now if you look at it, this quantity is very interesting, I am going to call this as the error of the prediction error at time instant $N+1$. What is this quantity; now look at this $e(N+1)$, let us examine this a little closely.

(Refer Slide Time: 15:58)

The image shows a whiteboard with handwritten mathematical equations and annotations. At the top, there is a small red scribble that looks like 'R=1'. The main equation is
$$e(N+1) = \frac{y(N+1) - \hat{h}(N)x(N+1)}{1}$$
 where the denominator is a simple '1'. Below this, there is a pink arrow pointing to the term $e(N+1)$ with the text "Prediction Error at time N+1." Below that, the equation $y(N+1) = h x(N+1) + v(N+1)$ is written. Underneath, the expression $y(N+1) - \hat{h}(N)x(N+1)$ is written, with a pink arrow pointing to it from the text "Prediction Error" written below. The text "Prediction of $y(N+1)$ " is written below the expression, and a pink line is drawn under the entire expression.

e_{N+1} equals $y_{N+1} - \hat{h}_N x_{N+1}$ and what I am calling this, I am calling this as your prediction error at time instant $N+1$. This is e_{N+1} , this is your prediction error at time instant $N+1$, the prediction error, this is the prediction error e_{N+1} which is $y_{N+1} - \hat{h}_N x_{N+1}$, this we are calling the prediction error e of $N+1$ at time instant $N+1$.

And the reason is very straightforward, now if you look at this, we have at time instant $N+1$, y_{N+1} equals $h x_{N+1} + v_{N+1}$. Now therefore if you look at this quantity $y_{N+1} - \hat{h}_N x_{N+1}$ - what you look at this is basically your \hat{h}_N , so basically you have your estimate \hat{h}_N at time instant N . Therefore, $\hat{h}_N x_{N+1}$, what is this quantity? This quantity is basically what your prediction of y_{N+1} .

So at time instant N you have your estimate \hat{h}_N correct. So if you do not know y_{N+1} that is the symbol the output symbol, what the output symbol y_{N+1} is going to be, you simply do $\hat{h}_N x_{N+1}$ that is going to give you an estimate of y_{N+1} at time instant at time instant $N+1$, right. So $\hat{h}_N x_{N+1}$ is the prediction of y_{N+1} at time instant $N+1$.

And therefore $y_{N+1} - \hat{h}_N x_{N+1}$ is the prediction error. And that is basically the real reason, correct. So this \hat{h}_N this what is this; this is your prediction of y_{N+1} and therefore this is the by naturally the actual symbol - the prediction that is, $y_{N+1} - \hat{h}_N x_{N+1}$, this is the prediction error at time instant $N+1$, okay.

So this quantity $y_{N+1} - \hat{h}_N x_{N+1}$, this basically tells you this prediction error tells you how good your estimate \hat{h}_N is at time instant N . Because if \hat{h}_N is very accurate the estimate is very accurate, then you expect $y_{N+1} - \hat{h}_N x_{N+1}$ to be very small because $\hat{h}_N x_{N+1}$ is a good predictor of y_{N+1} .

On the other hand, if the estimation error itself is large, then the prediction is going to be off right, so you are going to have a large prediction error and that is the key component in this sequential estimation scheme that is the prediction error and the update naturally depends on the prediction error because if the prediction error is large, that means you have a poor estimate, right.

Therefore you have to update by a larger quantity, but on the other hand if your prediction error is small, then that means you already have a very good estimate, so therefore you do not need to change your estimate by much. So you do not need to update by much or basically the magnitude of the update itself is going to be small.

And that is the important aspect that one has to realise in the sequential estimation, okay. Now let us look at this quantity over here, this other quantity. So we have looked at the prediction error, now let us look at this other quantity, now this other quantity, let us simplify this a little bit, so consider now the other quantity that is your x_{N+1} divided by what is that?

(Refer Slide Time: 20:28)

Prediction of y_{N+1}
Prediction Error

Consider now

$$\frac{x_{N+1}}{\sum_{k=1}^N x^2(k) + x^2(N+1)} = K(N+1)$$
Gain at time $N+1$

That is submission k equal to 1 to $N \times$ square of $k + x$ square of $N + 1$. Let us call this as k_{N+1} what is that? This is your gain, this is termed as the gain, and this is termed as the gain at

time $N + 1$. And now look at this quantity submission k equal to 1 to N x square of k now submission k equal to 1 to N of x square of k if you remember if you go all the way back over here, if you look at the variance, now look at this, from this I can write.

Basically, submission k equal to 1 to N x square of k that is submission let me just write it over here.

(Refer Slide Time: 21:25)

Estimate at time instant N .

$$\hat{h}(N) \sum_{k=1}^N x^2(k) = \sum_{k=1}^N x(k)y(k).$$

$$P(N) = \frac{\sigma^2}{\|\bar{x}\|^2} = \frac{\sigma^2}{\sum_{k=1}^N x^2(k)}.$$

$\sum_{k=1}^N x^2(k) = \frac{\sigma^2}{P(N)}$ variance of estimate at time N .

Consider now pilot symbol $x(N+1)$ and output symbol $y(N+1)$.

$$y(N+1) = h x(N+1) + v(N+1).$$

That your submission k equal to 1 to N x square of k is nothing but Sigma square times is nothing but Sigma square divided by p of N . From this relation over here, you can see that submission k equal to 1 to N in the denominator submission k equal to 1 to N x square k .

If I bring it to the left, then I have submission k equal to 1 to N x square k equals Sigma square over p N . Now I am going to substitute that over here. Remember p N is the variance at time instant N .

(Refer Slide Time: 22:08)

The image shows a whiteboard with handwritten mathematical equations and annotations. The top equation is the Kalman gain update equation:
$$K(N+1) = \frac{x(N+1)p(N)}{\sigma^2 + p(N)x^2(N+1)}$$
 Annotations include:

- A green arrow pointing to $x(N+1)$ labeled "Pilot symbol at N+1".
- An arrow pointing to σ^2 labeled "Noise variance".
- An arrow pointing to $p(N)$ labeled "variance at time N".
- The entire equation is labeled "Update Equation".

 The bottom equation is the state estimate update equation:
$$\hat{h}(N+1) = \hat{h}(N) + K(N+1)e(N+1)$$
 Annotations include:

- An arrow pointing to $\hat{h}(N+1)$ labeled "Estimate at time N+1".
- An arrow pointing to $\hat{h}(N)$ labeled "Estimate at time N".
- An arrow pointing to $K(N+1)$ labeled "Gain at time N+1".
- An arrow pointing to $e(N+1)$ labeled "Prediction Error at time N+1".

So this implies your k_{N+1} , the gain at time instant $N+1$ is basically x_{N+1} divided by σ^2 divided by p_N the variance at time instant $N+1$, which is equal to now simplify this as follows.

x_{N+1} times your quantity p_N divided by $\sigma^2 + p_N x^2_{N+1}$ and what is this? This is your gain k_{N+1} at time instant $N+1$ and therefore now we have explained expressed the gain as basically look at this, this depends only on what is the σ^2 ? This is the noise variance of noise v , yeah. What is p_N ? This is variance at time instant N .

And of course x_{N+1} , this is the pilot symbol at $N+1$ rather, pilot symbol at time $N+1$. And therefore now we have this k_{N+1} and now therefore, we have this quantity which is the gain k_{N+1} this quantity which is the error e_{N+1} and therefore the update remember, this is what is this? This is \hat{h}_{N+1} therefore, the update \hat{h}_N and that is important update \hat{h}_N .

Your update is basically \hat{h}_N equals or \hat{h}_{N+1} equals remember \hat{h}_{N+1} your k_{N+1} , the gain at time instant $N+1$ times e_{N+1} , the prediction error at time instant $N+1$ and that is the important thing to remember. So what do we have? What is interesting about this equation, so this is the estimate at time instant $N+1$. What is this? This is basically your estimate at time N .

This is your estimate at time N , this is the gain at time $N+1$, this is the gain of your estimating filter at time $N+1$ and this is an important quantity, this is what we have already

seen e_{N+1} , this is the prediction error at $N+1$ and therefore now what we have derived is basically we have derived an update equation for the estimated $N+1$ without recomputing the estimate.

So \hat{h}_{N+1} that is the estimated time $N+1$ equals \hat{h}_N which is the latest estimate that is estimate at time N + the gain k_{N+1} at time instant $N+1$ times e_{N+1} which is the prediction error at time instant $N+1$. And therefore now what we have is basically we have the update equation and this is important to realise, what we have? We have the update equation and we do not need to recompute.

And therefore it is not necessary to recompute the estimate, it is simply one can simply update the estimate, simply update the estimate update your estimate. Simply update your estimate, it is not necessary to recompute the estimate and if you look at this. You will realise that this depends only on \hat{h}_N and k_{N+1} and e_{N+1} . Now look at k_{N+1} .

(Refer Slide Time: 26:48)

The image shows a handwritten derivation on a whiteboard. At the top, it says "Consider now" and "Gain at time N+1". The main equation is
$$k(N+1) = \frac{x(N+1)}{\sum_{k=1}^N x^2(k) + x^2(N+1)}$$
 A pink circle highlights the denominator. Below this, it is simplified to
$$\Rightarrow k(N+1) = \frac{x(N+1)}{\frac{\sigma^2}{P(N)} + x^2(N+1)}$$
 The bottom part of the whiteboard shows
$$k(N+1) = \frac{x(N+1)P(N)}{\sigma^2 + P(N)x^2(N+1)}$$
 with annotations: "Pilot symbol at N+1" pointing to $x(N+1)$, "Noise variance" pointing to σ^2 , and "variance at time N" pointing to $P(N)$. The entire bottom section is labeled "Update Equation".

k_{N+1} depends only on p_N and x_{N+1} . Similarly, prediction error e_{N+1} depends only on y_{N+1} , x_{N+1} and \hat{h}_N , so basically what you can realise is that this entire equation, update equation for \hat{h}_{N+1} does not anywhere use the previous either pilot symbols x_1, x_2 up to x_N or the previous output symbols y_1, y_2 up to y_N okay. So all we are using is basically \hat{h}_N the estimate at time instant N , right.

P_N , the variance at time instant N okay and y_{N+1} that is the output at time instant $N+1$ and x_{N+1} which is the pilot symbol at time instant $N+1$. So these are basically the only things that we are using. We are not recomputing the estimate basically, we are only updating

the estimate and that is the important point to realise over here that we are simply updating the estimate okay.

And this is the update equation for the estimate, so at this update equation as we have said uses only.

(Refer Slide Time: 28:09)

The image shows a handwritten slide with the following content:

$$\hat{h}(N+1) = \hat{h}(N) + \dots$$

Annotations on the slide:

- An arrow points from $\hat{h}(N+1)$ to "Estimate at Time N+1".
- An arrow points from $\hat{h}(N)$ to "Estimate at time N".
- An arrow points from the plus sign to "Gain at time N+1".
- An arrow points from the ellipsis to "Prediction Error at time N+1".
- A note says "Simply update Estimate NOT necessary to recompute." with an arrow pointing to the equation.
- A note says "update Equation uses only $y(N+1), x(N+1), p(N), \hat{h}(N)$." with an arrow pointing to the equation.

The update equation uses only your y_{N+1} , x_{N+1} , p_N and \hat{h}_N all right. So nowhere are we using the previous pilot symbols x_1, x_2 up to x_N or the previous outputs y_1, y_2 up to y_N .

So all the information that corresponds to the previous pilot symbols and the previous output symbols so as to speak is encapsulated, right is present in \hat{h}_N and p_N , right. So in that sense we do not need to use the previous pilot symbols, we can simply use \hat{h}_N and update the estimate to \hat{h}_{N+1} . Now other quantity that we obviously have to update is the variance that is p_{N+1} and that can also be simply calculated as follows.

So update for the update for the error variance, now the update for the error variance is basically now you can see p_{N+1} .

(Refer Slide Time: 29:26)

update Equation uses only $y(N+1)$, $x(N+1)$, $P(N)$, $h(N)$.

Update For Error Variance:

$$P(N+1) = \frac{1}{\sum_{k=1}^{N+1} x^2(k)}$$

The variance is basically 1 over now let us look at again let us first recompute the estimate and then we will see how it can be updated similar to what we have done before, you can if you go way back you can see p_N equals Sigma square divided by submission k equal to 1 to N x square of k .

So this N I can replace by $N + 1$ and I can get the variance that is the variance at time instant $N + 1$ that is p_{N+1} equals 1 over submission k equal to 1 to $N + 1$ your x square of k , which I am going to again right it by splitting this into term corresponding to submission up to k .

(Refer Slide Time: 30:11)

$$= \frac{\sigma^2}{\sum_{k=1}^N x^2(k) + x^2(N+1)}$$
$$= \frac{\sigma^2}{\frac{\sigma^2}{P(N)} + x^2(N+1)}$$

That is submission up to N that is k equal to 1 to N submission x square of k + term corresponding to N + 1 that is x square of N + 1.

In fact, let me just write this little clearly this is x square of k. Now we know that this quantity submission k equal to 1 to N x square of k, this is nothing but Sigma square divided by p N, that is what we have already, submission k equal to 1 to N x square k is Sigma square divided by p N, that is something that we have already seen. Therefore, now this is your 1 over Sigma square, 1 over.

I am sorry, this is not 1 over, this is Sigma square divided by the numerator there is Sigma square, so there is basically Sigma square divided by p N + x square of N + 1 and therefore now I can simplify this as.

(Refer Slide Time: 31:23)

The image shows a whiteboard with handwritten mathematical equations. At the top left, it says "Variance at time N+1." with an arrow pointing to the first equation. The equations are:

$$p(N+1) = \frac{\sigma^2 p(N)}{\sigma^2 + p(N) x^2(N+1)}$$

$$= \left(\frac{\sigma^2}{\sigma^2 + p(N) x^2(N+1)} \right) p(N)$$

Basically Sigma square times p N divided by Sigma square + p N times x square N + 1, this is your p N + 1 and remember what if p N + 1; this is the variance at time N + 1. And what is this equal to; this is equal to well I can write this as, let me take this p N outside, so I can write this as Sigma square divided by Sigma square + p N into x square N + 1 times p N and what is this; this is basically now I can write this as.

(Refer Slide Time: 32:30)

$$= \left(1 - \frac{p(N)x^2(N+1)}{\sigma^2 + p(N)x^2(N+1)} \right) p(N).$$

$$= \left(1 - \frac{p(N)x(N+1)}{\sigma^2 + p(N)x^2(N+1)} x(N+1) \right) p(N).$$

$$=$$

1 - p N into x square N + 1 divided by Sigma square + p N into x square N + 1 into p N, which is equal to, what is this equal to; this is equal to your 1 -, now let us look at this.

I have this quantity p N x N + 1 divided by Sigma square + p N x square N + 1 times x N + 1 times p N and now if you look at this, now look at this quantity p N into x N + 1 divided by p N, if you look at this quantity, this is your p N into x N + 1 divided by Sigma square plus p n into x square N + 1. If you go all the way up over here and you can see this quantity is nothing but your gain k N + 1.

(Refer Slide Time: 33:46)

$$\Rightarrow k(N+1) = \frac{x(N+1)}{\frac{\sigma^2}{p(N)} + x^2(N+1)}$$

$$k(N+1) = \frac{x(N+1)p(N)}{\sigma^2 + p(N)x^2(N+1)}$$

Update Equation

$$\hat{h}(N+1) = \hat{h}(N) + k(N+1)e(N+1)$$

And therefore, now I can get it into a form.

(Refer Slide Time: 33:53)

$$= \left(1 - \frac{p(N)x(N+1)}{\sigma^2 + p(N)x^2(N+1)} \right) p(N).$$

$$= \left(1 - \frac{p(N)x(N+1)}{\sigma^2 + p(N)x^2(N+1)} x(N+1) \right) p(N).$$

$$p(N+1) = \left(1 - k(N+1)x(N+1) \right) p(N).$$

Labels for the Kalman gain equation:

- Variance at time N+1 (points to $p(N+1)$)
- Gain at time N+1 (points to $k(N+1)$)
- Pilot symbol at time N+1 (points to $x(N+1)$)
- Variance at time N (points to $p(N)$)

So I have p_{N+1} , the variance at time instant $N+1$ is $1 - k_{N+1}$ into x_{N+1} into p_N . And that is basically your variance update at, this is your variance at time instant $N+1$, p_{N+1} is variance at time instant $N+1$, p_N is variance at time N , k_{N+1} is gain at time $N+1$ and x_{N+1} is of course this is your pilot symbol at time $N+1$.

This is your pilot symbol at time $N+1$. And therefore now you can once again update the variance p_{N+1} corresponding to time instant $N+1$, p_{N+1} equals $1 - k_{N+1}$ times x_{N+1} into p_N . Basically, the variance at time instant N . So basically, if you know the variance p_N at time instant N and \hat{h}_N at time instant N , after observing y_{N+1} that is knowing the pilot symbol x_{N+1} at time instant $N+1$.

And observing the output y_{N+1} at time instant y_{N+1} , I can basically update the estimate from \hat{h}_N to \hat{h}_{N+1} okay that is what we have seen previously, \hat{h}_{N+1} equals \hat{h}_N estimated time instant N plus the gain k_{N+1} at time instant $N+1$ times e_{N+1} , which is the prediction error at time instant e_{N+1} . And of course the variance at time instant $N+1$ p_{N+1} , we are updating this as $1 - k_{N+1}$ into x_{N+1} times p_N , all right.

So you update both the estimated time instant $N+1$ and the variance at time instant $N+1$ and then move forward again to time instant $N+2$ using basically the symbol x_{N+2} and output y_{N+2} . And this sequential, now this procedure sequential procedure of course we have illustrated it for N to $N+1$, 1 similarly now repeat this at $N+2$ and so on naturally, this is the sequential estimation procedure.

So basically what you have to keep in mind is basically the update equations for any sequential estimation procedure.

(Refer Slide Time: 36:41)

The image shows a handwritten derivation on a whiteboard. At the top, there is a circled expression $\sum_{k=1}^N x^{(k)} + x^{(N+1)}$. Below it, the variance at time $N+1$ is derived as follows:

$$\text{Variance at time } N+1 = \frac{\sigma^2}{\frac{\sigma^2}{P(N)} + x^2(N+1)}$$

$$P(N+1) = \frac{\sigma^2 P(N)}{\sigma^2 + P(N) x^2(N+1)}$$

$$= \left(\frac{\sigma^2}{\sigma^2 + P(N) x^2(N+1)} \right) P(N)$$

Basically, this is a very big area which ties to sequential estimation for instance for things such as the Kalman filter and so on, which basically estimates a quantity which is continuously varying and the structure is the same. Basically, you have an estimate; basically you have an update equation for the estimate at time $N + 1$. This is the update equation for the estimate.

(Refer Slide Time: 37:02)

The image shows a handwritten derivation on a whiteboard. At the top, the Kalman gain $K(N+1)$ is defined as:

$$K(N+1) = \frac{x^{(N+1)} P(N)}{\sigma^2 + P(N) x^2(N+1)}$$

Annotations include: "Noise variance" pointing to σ^2 , "variance at time N" pointing to $P(N)$, and "Update Equation for Estimate" under the fraction. Below this, the estimate update equation is shown:

$$\hat{h}(N+1) = \hat{h}(N) + K(N+1) e(N+1)$$

Annotations include: "Estimate at Time N+1" pointing to $\hat{h}(N+1)$, "Estimate at time N" pointing to $\hat{h}(N)$, "Gain at time N+1" pointing to $K(N+1)$, and "Prediction Error at Time N+1" pointing to $e(N+1)$. A note says "Simply update Estimate NOT necessary to recompute." At the bottom, it says "Update Equation uses only".

Let me write this update equation for estimate. So you have 2 update equations, you have the update equation for the estimate and then you have this update equation for the variance, so this is your update equation for the variance.

(Refer Slide Time: 37:20)

The image shows a handwritten equation on a whiteboard:
$$P(N+1) = [I - K(N+1)X(N+1)]P(N)$$
 The equation is annotated with blue arrows and text:

- An arrow points from $P(N+1)$ to the text "Variance at time N+1".
- An arrow points from $[I - K(N+1)X(N+1)]$ to the text "Gain at time N+1".
- An arrow points from $P(N)$ to the text "Variance at time N".
- Below the equation, the text "Pilot symbol at time N+1." is written in red.
- Below the equation, the text "Update Equation For variance." is written in blue, with an arrow pointing from the entire equation towards it.

And put together, they constitute basically your sequential estimation procedure, okay. This is the update equation. This is the update equation for the variance and put together, so we have an update equation for the estimate, update equation for the variance and put together basically we have the net sequential estimation procedure that is very interesting.

So so what we have described in this module; basically we have completed the discussion of the sequential estimation procedure where we are not recomputing the estimated time instant, we are rather using the estimated time instant N that a \hat{h} of N and the variance p of N at time instant N and using this and the corresponding pilot symbol and observation x_{N+1} and y_{N+1} at time instant $N+1$, right.

And we are basically updating the estimate from \hat{h}_N to \hat{h}_{N+1} , updating the variance from p_N to p_{N+1} and this is basically a sequential estimation procedure because this can be now sequentially repeated at time instant $N+2$, $N+3$ and so on without the necessity to recompute the estimate at every time instant, all right. So this module basically comprehensively describes the paradigm of sequential estimation, okay.

So we will stop this module over here and we will continue with an example of the sequential estimation procedure in the subsequent module, thank you very much.
