Reliability of the Maximum Likelihood (ML) Estimate - Number of Samples Required

Hello, welcome to another module in this massive open online course on Estimation Theory for Wireless Communication. So far we have looked at the Maximum Likelihood Estimate which is a sample mean. For a simple example of a wireless sensor and with N observations we have looked at the Maximum Likelihood Estimate.

And we have looked at the properties of Maximum Likelihood Estimate. That is the mean and the variant of the Maximum Likelihood Estimate. And we have seen some interesting properties of this Maximum Likelihood Estimate. Today what we are going to do is, we are going to explore this Maximum Likelihood Estimate further.

Let us look at the reliability of this Maximum Likelihood Estimate. So what we are going to start looking at today is another example another simple example. We are going to explore the reliability of this, of this maximum likely hood or basically the ML. The reliability of the Maximum Likelihood Estimate. Namely, what is the number of samples for instance, what is the number of samples required for estimation?

(Refer Slide Time: 01:44)

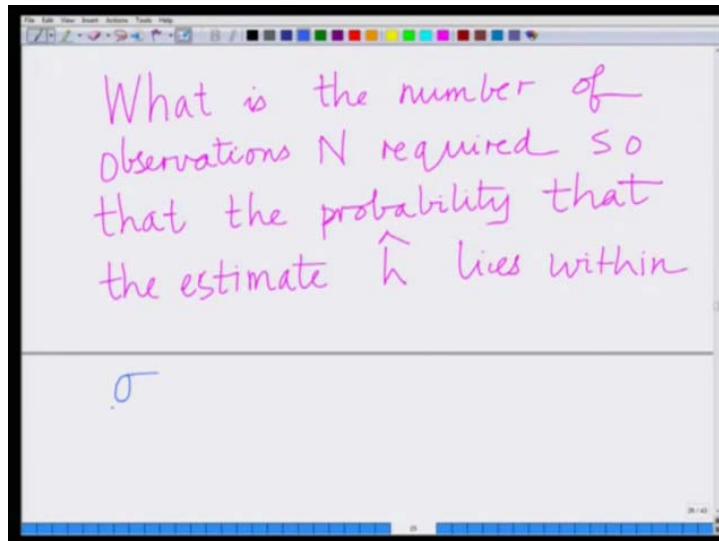

Number of samples or number of observations. Number of observations in required for estimation of a particular accuracy. So what we are going to start addressing today is, what is

this number of, how do we decide the number of samples required for estimation? That is how do we how do we how do we choose this number of samples capital N that is required for estimation to achieve a certain degree of reliability?

That is, how do we decide the reliability of this Maximum Likelihood Estimate and it is not easy task because we said that this Maximum Likelihood Estimate \hat{h} is random in nature. So it is, it is quite challenging and we are going to look at how to decide the number of samples N that is required. So basically the approach that you're going to employ is basically one that involves the probability.

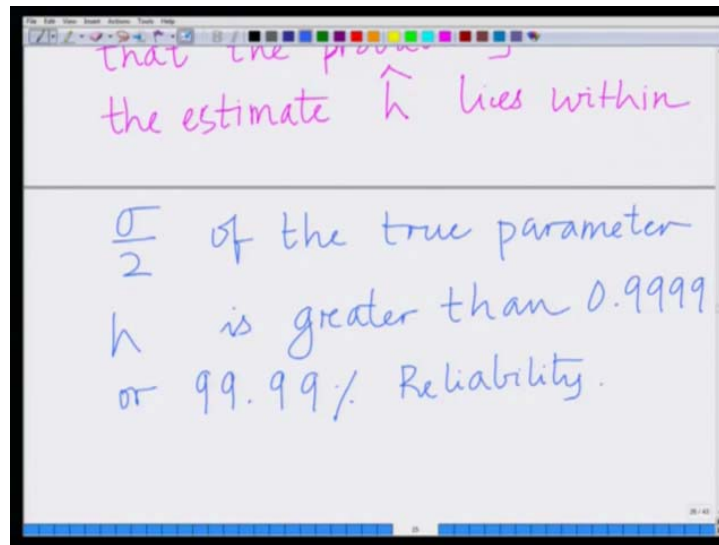

Yeah, so we are going to choose, so we're going to address so we can formulate this question in this fashion.

(Refer Slide Time: 03:11)

We're going to ask the question; what is the number of observations N that is required so that the probability of the estimate \hat{h} lies within Sigma by 2.

(Refer Slide Time: 04:22)

Lies within Sigma by 2 of the true parameter of the true parameter h is greater than 0.9999 or basically 99.99% reliability. One can also call this one can also define this notion, this probabilistic notion as basically reliability. So what we are saying is basically that probability can be used as a measure of reliabilities, since the estimate \hat{h} is random in nature.

And now we are asking this interesting question. What is this number of observations capital N that is required such that the estimate \hat{h} lies within a distance or lies within the radius of Sigma by 2 from the true parameter h with probability that is greater than 0.9999 or basically with 99.99% reliability or 99.99% certainty?

So let us illustrate this pictorially, so what we have is basically we have your estimate which is distributed as a Gaussian random variable.

(Refer Slide Time: 06:14)

We said the estimate is a Gaussian random variable with mean centered around h , h is the mean. And if we take a Sigma by 2 radius around the mean that is this is $h + \text{Sigma by 2}$ and this $h - \text{Sigma by 2}$, so this is the Sigma by 2 radius around the true parameter h .

And we are saying, what is the number of observation in that is required such that the estimate the estimate \hat{h} lies in this range with 99.99% certainty or with 99.0. lies in this range with probability greater than 0.9999.

So when you are saying what is the probability that this life within a radius that is the estimate \hat{h} lies within the radius Sigma by 2 of the true parameter h with probability greater than 0.9999 or greater than 99.99% of the time okay. And this can be found as follows, so basically we are asking the question.

(Refer Slide Time: 08:15)

$$\Pr\left(|\hat{h} - h| \leq \frac{\sigma}{2}\right) \geq 0.9999$$
$$\Rightarrow \Pr\left(|\hat{h} - h| \geq \frac{\sigma}{2}\right) \leq 1 - 0.9999 = 0.0001$$

w Estimation error

$$\frac{\hat{h} - h}{\text{Estimate} - \text{True Parameter}} = \frac{w}{ES}$$

The probability that your estimate - the true parameter that is the radius, that is the estimate minus the true parameter should be less than or equal to radius Sigma by 2 that is, \hat{h} should lie within Sigma by 2 radius of h with probability greater than 0.9999 and that implies basically, now realise that this. Basically what that implies is that implies that the probability that it lies outside this radius.

So, naturally $\hat{h} - h$ is greater than or equal to Sigma by 2 less 1 - 0.9999 that is equal to 0.0001. That is the probability; it lies outside of the radius Sigma by 2. It should be less than 1 - 0.9999 that is 0.0001.

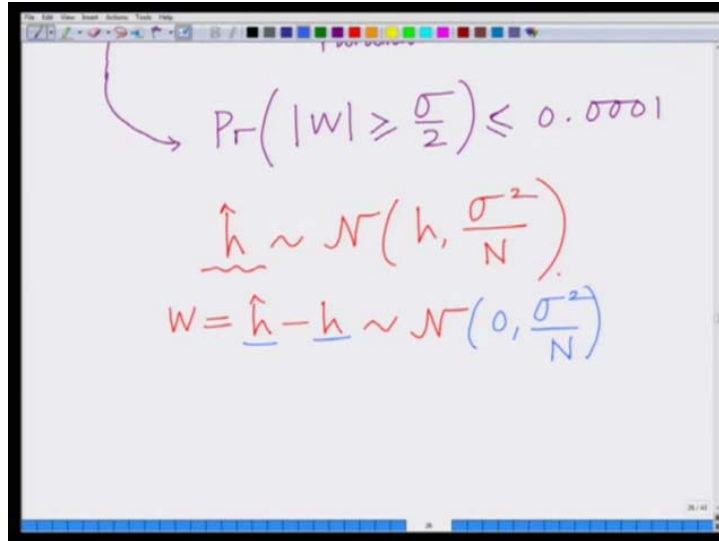

So what we are saying is the probability that it should lie within a radius of Sigma by 2 should be greater than or equal to 0.9999 which automatically mean that the probability it lies outside the radius Sigma by 2 should be less than 1 - 0.9999 that is 0.0001 that is 99.99% of the time it should lie within the radius of Sigma by 2 which means only 0.01 of time it can lie outside the radius Sigma by 2.

And now you will realise that this $\hat{h} - h$, this is nothing but our quantity w which is the estimation error. This $\hat{h} - h$, \hat{h} is the estimate; h is the true parameter and this $- h$. So this is your estimate and this is basically your true parameter and therefore $\hat{h} - h$ is equal to w which is basically the, which is basically the estimation error.

And therefore what we are asking is, we are asking basically, what is the probability that this estimation error that is the probability that this estimation error, magnitude of this estimation error should be greater than or equal to Sigma by 2. Only point with probability 0.001 or

0.01% of the time. And now realise something important, we said that the estimate \hat{h} is Gaussian with mean h and variance σ^2 divided by N .

(Refer Slide Time: 11:36)

A whiteboard with a black border and a toolbar at the top. The toolbar contains various drawing tools like a pen, eraser, and selection tools. The whiteboard contains three lines of handwritten mathematical equations. The first line is $P_r(|W| \geq \frac{\sigma}{2}) \leq 0.0001$ written in purple ink, with a purple arrow pointing from the left towards the equation. The second line is $\hat{h} \sim \mathcal{N}(h, \frac{\sigma^2}{N})$ written in red ink, with a red wavy underline under the \hat{h} . The third line is $W = \hat{h} - h \sim \mathcal{N}(0, \frac{\sigma^2}{N})$ written in blue ink, with blue underlines under the \hat{h} and h .

Remember, yesterday we derived two important properties of the Maximum Likelihood Estimate in the previous module. That is, we said \hat{h} is an unbiased estimate which means expected value of \hat{h} is h , that is \hat{h} is Gaussian distributed with mean h and it has a variance equal to σ^2 divided by N .

And therefore now if you look at w which is basically from \hat{h} which you from \hat{h} you subtract h which is the mean therefore, naturally this will become a 0 mean random variable. So w is Gaussian distributed with mean 0 and variance σ^2 divided by N . w is the estimation error which is $\hat{h} - h$. So from \hat{h} you are subtracting the mean.

(Refer Slide Time: 12:36)

The image shows a whiteboard with handwritten mathematical derivations. At the top, there is a purple arrow pointing to the equation $Pr(|W| \geq \frac{\sigma}{2}) \leq 0.0001$. Below this, the estimator \hat{h} is shown to follow a normal distribution: $\hat{h} \sim \mathcal{N}(h, \frac{\sigma^2}{N})$. The estimation error w is defined as $w = \hat{h} - h$, which is also shown to follow a normal distribution: $w \sim \mathcal{N}(0, \frac{\sigma^2}{N})$. A blue arrow points from the mean 0 in the second distribution to the text "mean 0". Finally, the probability density function $f_W(w)$ is given as $f_W(w) = \frac{1}{\sqrt{2\pi\frac{\sigma^2}{N}}} \cdot e^{-\frac{Nw^2}{2\sigma^2}}$.

Therefore, w is Gaussian distributed with mean 0 and variance that is if you subtract the mean from a random variable, you get 0 mean random variables say for w which is the estimation error is 0 mean and has a variance Sigma square divided by N .

This is Gaussian in nature, so the probability density function f_w of w is given as 1 over square root of 2 pie times the variance that is the Sigma square divided by N e raise to - $N w$ square divided by 2 Sigma square.

So the Probability Density Function of the estimation error is Gaussian with mean 0, variance Sigma square divided by N and therefore, the Probability Density Function 1 over square root 2 pie Sigma square divided by N e raise to - $N w$ square divided by 2 Sigma square.

(Refer Slide Time: 13:44)

$$\Pr(|W| \geq \frac{\sigma}{2}) \leq 0.0001$$
$$\Rightarrow \Pr(W \geq \frac{\sigma}{2}) + \Pr(W \leq \frac{\sigma}{2}) \leq 0.0001.$$

And now therefore we are asking what is the probability, the question that we are asking is what is the probability that mode w is greater than or equal to Sigma by 2 should be less than or equal to 0.001.

Which implies that the probability w is greater than or equal to Sigma by 2 + the probability w is less than or equal to Sigma by 2, should be less than or equal to 0.001 because magnitude of w is greater than or equal to Sigma 2 when w is greater than or equal to Sigma by 2 or w is less than or equal to sorry there should be a - Sigma by 2 over here.

And now each of these quantities, probability of w is greater than or equal to Sigma by 2.

(Refer Slide Time: 14:45)

$$\Rightarrow \Pr(W \geq \frac{\sigma}{2}) + \Pr(W \leq -\frac{\sigma}{2}) \leq 0.0001.$$
$$\Rightarrow \int_{\frac{\sigma}{2}}^{\infty} F_W(w) dw + \int_{-\infty}^{-\frac{\sigma}{2}} F_W(w) dw \leq 0.0001$$

This is nothing but integral, the Probability Density Function of w between $\sigma/2$ to infinity, that is as of w W integral between 0 to infinity + the probability that it is less than or equal to $-\sigma/2$ is integral $-\infty$ to $-\sigma/2$.

The Probability Density Function of w which we are saying should be less than or equal to 0.0001. Now observe that this Probability Density Function is an even function therefore, we have f of w of w is basically equal to f of w of $-w$, which means this integral both these integrals are equal. The integral from $\sigma/2$ to infinity is equal to the integral from $-\infty$ to $-\sigma/2$.

(Refer Slide Time: 15:42)

The image shows a whiteboard with handwritten mathematical equations. At the top, it states $f_w(w) = f_w(-w)$. Below this, an arrow points to the equation $\Rightarrow 2 \int_{\sigma/2}^{\infty} f_w(w) dw \leq 0.0001$. A second arrow points to the equation $\Rightarrow \int_{\sigma/2}^{\infty} f_w(w) dw \leq 0.00005$. The whiteboard also features a toolbar at the top and a blue taskbar at the bottom.

Therefore, this implies basically that twice the integral from $\sigma/2$ to infinity of f of w W $d w$ less than or equal to 0.0001 which basically implies that the integral from $\sigma/2$ to infinity f of w of w $d w$ less than or equal to 0.00005 that is 0.0001 divided by 2. And therefore what we have derived is that we have derived the equivalent condition in terms of the estimation error W .

We have said, for the probability that basically the estimation that the \hat{h} should lie within a $\sigma/2$ radius of the true parameter h with probability greater than or equal to 99.99% that is 0.9999 that is equivalent to the condition that the estimation error should lie between that is equal to their that is equal to the probability that the magnitude of the estimation error should lie outside.

That it should be greater than or equal to $\sigma/2$ with probability less than or equal to 0.0001 which is basically reduced to this integral condition that is the integral evaluated

between Sigma by 2 to infinity f of w d w should be less than or equal to 0.00005 that is the condition that we have derived.

Now let us simplify this integral, we know the Probability Density Function, we are given the Probability Density Function lets us substitute this Probability Density Function of this random variable w which is the estimation and we know that we have derived here Probability Density Function.

(Refer Slide Time: 17:48)

The image shows a whiteboard with handwritten mathematical equations. At the top, the probability density function $f_W(w)$ is given as $\frac{1}{\sqrt{2\pi\sigma^2/N}} \cdot e^{-\frac{Nw^2}{2\sigma^2}}$. Below this, the probability $\Pr(|W| \geq \frac{\sigma}{2}) \leq 0.0001$ is written. This is then expanded to $\Pr(W \geq \frac{\sigma}{2}) + \Pr(W \leq -\frac{\sigma}{2}) \leq 0.0001$. Finally, the corresponding integrals are shown: $\int_{\frac{\sigma}{2}}^{\infty} f_W(w) dw + \int_{-\infty}^{-\frac{\sigma}{2}} f_W(w) dw$.

That is 1 over square root of 2 pie Sigma square divided by N e raise to - N W square divided by 2 Sigma square.

Therefore if we substitute this over here.

(Refer Slide Time: 18:13)

$$\Rightarrow \int_{-\sigma/2}^{\sigma/2} F_W(w) dw \leq 0.00005$$

$$\Rightarrow \int_{-\sigma/2}^{\sigma/2} \frac{1}{\sqrt{2\pi\sigma^2/N}} e^{-\frac{Nw^2}{2\sigma^2}} dw \leq 0.$$

We have the condition $\int_{-\sigma/2}^{\sigma/2} F_W(w) dw \leq 0.00005$, we have the condition $\int_{-\sigma/2}^{\sigma/2} \frac{1}{\sqrt{2\pi\sigma^2/N}} e^{-\frac{Nw^2}{2\sigma^2}} dw \leq 0.00005$. Now let us use the substitution

(Refer Slide Time: 18:45)

$$\frac{W^2}{\sigma^2/N} = \frac{NW^2}{\sigma^2} = t^2$$

$$\Rightarrow W = \frac{\sigma}{\sqrt{N}} t$$

$$\Rightarrow dw = \frac{\sigma}{\sqrt{N}} dt$$

$$\Rightarrow \int$$

Now let us use the substitution $\frac{W^2}{\sigma^2/N} = \frac{NW^2}{\sigma^2} = t^2$, which basically implies that w is equal to $\frac{\sigma}{\sqrt{N}} t$, which also basically implies that your dw equals $\frac{\sigma}{\sqrt{N}} dt$.

And now if you substitute this in this integral, we have, you can see the limits; this integral condition becomes $\int_{-\sigma/2}^{\sigma/2} F_W(w) dw$.

(Refer Slide Time: 19:38)

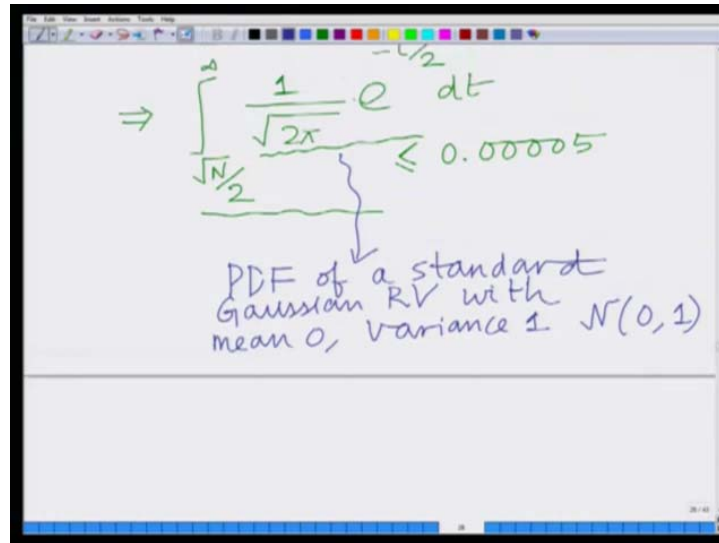

The image shows a whiteboard with handwritten mathematical work. At the top, there is an integral expression: $\int_{\frac{\sqrt{N}}{2}}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\frac{t^2}{2}} dt$. A pink arrow points to the upper limit ∞ . To the right, the expression $\frac{1}{\sqrt{N}}$ is written and crossed out with a red line. Below this, the inequality ≤ 0.00005 is written in red. In the middle, the integral is simplified to $\int_{\frac{\sqrt{N}}{2}}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-\frac{t^2}{2}} dt$ in green. Below this, the inequality ≤ 0.00005 is written in green.

We have t is basically w divided by σ divided by square root of N , so this becomes square root of N divided by 2 to infinity. Now $\frac{1}{\sqrt{2\pi}} \frac{1}{\sqrt{N}}$ or $\frac{1}{\sqrt{2\pi N}}$.

If I bring the σ^2 over N out that is σ divided by square root of N times e raised to of course $N w^2$ divided by σ^2 , this 2 square so e raised to $-\frac{t^2}{2}$ and dt is σ divided by $d w$ σ divided by square root of N dt .

And therefore, we have this σ divided by square root of n cancelling and what we have is basically this integral should be less than or equal to 0.0 or this integral should be less than or equal to 0.00005 and now if you look at this integral, we have this integral, square root of N over 2 to infinity $\frac{1}{\sqrt{2\pi}} e^{-\frac{t^2}{2}} dt$ or equal to 0.00005 and therefore now if you look at this.

(Refer Slide Time: 21:26)

$$\Rightarrow \int_{\frac{\sqrt{N}}{2}}^{\infty} \frac{1}{\sqrt{2\pi}} e^{-t^2/2} dt \leq 0.00005$$

PDF of a standard Gaussian RV with mean 0, variance 1 $\mathcal{N}(0,1)$

This is a well-known standard integral, so what we have is this condition that is integral square root of N over 2 to infinity $\frac{1}{\sqrt{2\pi}} e^{-t^2/2} dt$ should be less than or equal to 0.00005. Now this integral is a standard integral, if you look at this Probability Density Function that is $\frac{1}{\sqrt{2\pi}} e^{-t^2/2}$ divided by 2.

That is the Probability Density Function of a standard normal variable or standard Gaussian variable with mean 0 and variance 1. So if you look at this, $\frac{1}{\sqrt{2\pi}} e^{-t^2/2}$, this is the PDF of a standard. This is a PDF of a standard currency and RV with mean 0 variance 1 that is $\mathcal{N}(0,1)$, which implies and therefore this integral has a standard definition.

(Refer Slide Time: 23:01)

The image shows a whiteboard with handwritten mathematical equations. The first equation is $Q(x) = \int_x^{\infty} \frac{1}{\sqrt{2\pi}} e^{-t^2/2} dt$. The second equation is $= P_T(T \geq x)$. Below the second equation, there is a green arrow pointing to the 'T' in the probability expression, with the text 'Gaussian mean 0 variance 1.' written in green.

This integral is known as q of x. That is q of x is defined as a Gaussian q function, which is integral x to infinity 1 over square root of 2 pie e raise to - t square by 2 d t, which is the probability which is basically the probability that your standard Gaussian random variable t is greater than or equal to x.

This is the probability that your standard Gaussian random variable t which is Gaussian, mean 0 variance Gaussian with mean 0 and variance 1 is greater than or equal to x, this is the q function, q function is defined.

q of x is the probability that the Gaussian random variable with mean 0 and variance 1 is greater than or equal to x or basically lies between the interval x to infinity which is a integral from x to infinity 1 over square root of 2 pie e raise to - t square divided by 2 d t.

And therefore now if you look at this integral.

(Refer Slide Time: 24:18)

$$\Rightarrow \int_{\frac{\sqrt{N}}{2}}^{\infty} \frac{1}{\sqrt{2x}} e^{-\frac{t^2}{2}} dt \leq 0.00005$$

PDF of a standard Gaussian RV with mean 0, variance 1 $N(0,1)$

$$Q(x) = \int_x^{\infty} \frac{1}{\sqrt{2x}} e^{-\frac{t^2}{2}} dt$$

This integral over here is nothing but q of square root of n divided by 2, this is the q function, from here we are replacing x by square root of N by 2.

(Refer Slide Time: 24:43)

$$\Rightarrow Q\left(\frac{\sqrt{N}}{2}\right) \leq 0.00005$$
$$\Rightarrow \frac{\sqrt{N}}{2} \geq Q^{-1}(0.00005)$$
$$\Rightarrow N \geq (2Q^{-1}(0.00005))^2 = 60.574$$

Therefore, we have this reduces to the standard condition that q of square root of n by 2 has to be less than or equal to 0.00005 which implies basically now I simplify it in terms of the Gaussian q function.

Square root of n by 2 is greater than or equal to, q function is a decreasing function is greater than or equal to q inverse of 0.00005 which implies basically N has to be greater than or

equal to $2 \cdot q^{-1}(0.0005)$ the whole square is basically equal to 60.54 samples or observations.

(Refer Slide Time: 25:35)

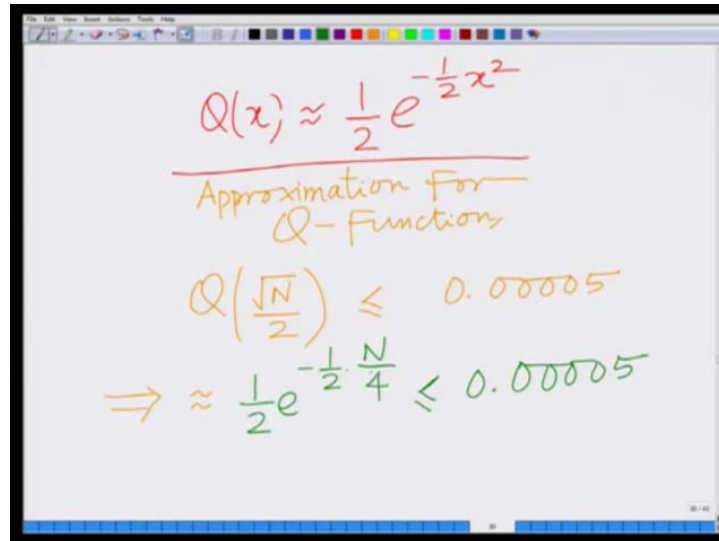

The image shows a whiteboard with handwritten mathematical derivations. At the top, there is a red arrow pointing to the equation $\frac{\sqrt{N}}{2} \geq Q^{-1}(0.0005)$. Below this, the equation is rearranged to $\Rightarrow N \geq (2Q^{-1}(0.0005))^2$, which is then simplified to $= 60.54$. Finally, the result is boxed in blue as $N \geq 61$.

Therefore, what the results that we have is N , since N is an integer, N has to be greater than or equal to 61 observations and this is an interesting result. What we have demonstrated here is basically to have a reliability of 99.99%, right. So what is the definition of reliability, the reliability here is that we want the estimate \hat{h} to lie within a Sigma by 2 radius of the true parameter h .

And what we are saying is if that has to happen with a probability greater than or greater than equal to 99.99% or a probability greater than or equal to 0.9999, then the minimum number of samples capital N that is required is basically your 61 sample. 61 samples are required with is the minimum number of sample that is required.

And now this the q function, this expression for this q function can be simplified a little bit further because there is no close form expression for the q function. One can approximate the q function as follows. So q of x can be approximated which we can will employ frequently, $-\frac{1}{2} e^{-\frac{1}{2} x^2}$, which means, so this is an approximation for your q function.

(Refer Slide Time: 27:05)

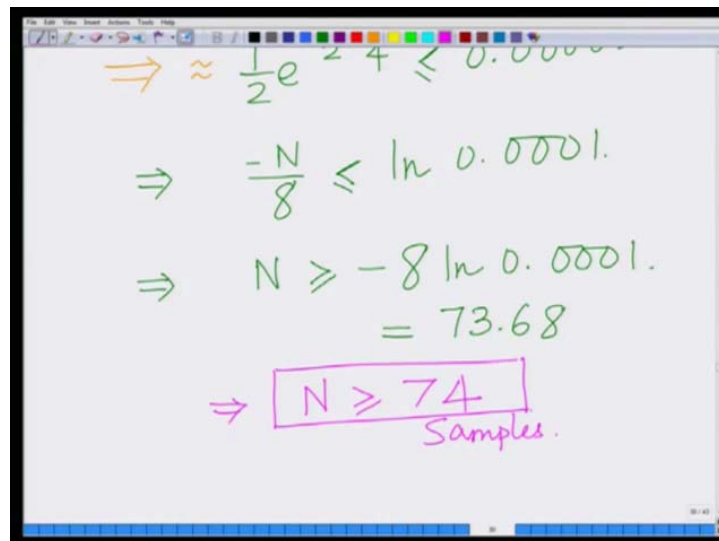

Handwritten notes on a whiteboard showing the approximation for the Q-function. The text is written in red and orange ink. At the top, the equation $Q(x) \approx \frac{1}{2} e^{-\frac{1}{2}x^2}$ is written. Below it, the text "Approximation for Q-Function" is written in orange. Then, the equation $Q\left(\frac{\sqrt{N}}{2}\right) \leq 0.00005$ is written in orange. Finally, the equation $\Rightarrow \approx \frac{1}{2} e^{-\frac{1}{2} \cdot \frac{N}{4}} \leq 0.00005$ is written in green.

So this is the approximation for the q function. So this is the approximation for the q function. And therefore now, one can also use this approximation, so q or square root of N by 2 less than or equal to 0.00005. Now q of square root of 2, I approximate it, which implies approximation half a power - half square, that is half e raise to - square root of N by to whole square.

That is N by basically 4 must be less than or equal to 0.00005 which basically implies that... Taking log on both sides.

(Refer Slide Time: 28:07)

Handwritten notes on a whiteboard showing the derivation of the minimum number of samples N. The text is written in green and pink ink. At the top, the equation $\Rightarrow \approx \frac{1}{2} e^{-\frac{N}{4}} \leq 0.00005$ is written in green. Below it, the equation $\Rightarrow \frac{-N}{8} \leq \ln 0.0001$ is written in green. Then, the equation $\Rightarrow N \geq -8 \ln 0.0001$ is written in green, followed by $= 73.68$. Finally, the equation $\Rightarrow N \geq 74$ is written in pink, with "Samples." written below it.

$-N$ divided by 8 less than or equal to \log to the base e or \log natural of twice 0.00005, which is 0.0001. Which means, it basically implies your N is greater than or equal to - 8 because there is a negative sign, the equality gets reversed.

N is greater or equal to $- 8 \log$ natural 0.0001 and this is basically equal to 73.68 and therefore since N has to be an integer, this implies basically that N has to be greater than or equal to 74. $N \geq 74$ samples which is again an interesting result.

So we have used this approximate, we have got this approximate value of N using the approximation for the q function which we have also employed frequently in this course because there is no close form expression for the q function and we will have to use the q function quite frequently to calculate the reliability of the estimate.

So what we have illustrated now is we have illustrated an interesting example. For instance, in the context of wireless sensor network, we have seen that a sensor node can keep receiving observations yeah and based on these observations we compute the likelihood function. From the likelihood function we compute the Maximum Likelihood Estimate. Maximum Likelihood Estimate is unbiased, it is Gaussian, it has variance $\text{Sigma Square by } N$.

Now, one can a now, we also said in the previous module that because the estimate \hat{h} is random, one can never be certain that it is not necessarily equal to h . In fact, it is not equal; because it is Gaussian it is equal. The probability that it is exactly equal to the true parameter h is 0. Yeah, so what we can say is, we have to come up with other notions of reliability and that is what we have tried to define in today's module.

How can we characterise, how accurate this random or this random estimate \hat{h} is. And one measure of reliability is that we said, it has to lie within a $\text{Sigma by } 2$ radius of h with a probability that is greater than or equal to 99.99% or 0.9999. And therefore, what is the sample, number of samples N that is required for that.

We said the number of samples that is required for that is approximately of the order of 60 to 70 samples that you require. So although, h is random we said in the previous module that as the number of samples increases, the variance of the estimate progressively decreases and therefore, the sample keeps, the sample lies closer.

The probability that sample lies close to the true estimate keeps increasing. And now we have used this property to calculate what is to characterise precisely, what is the number of samples required to achieve a certain degree of reliability.

So this is an example, an interesting example which relates this N to the reliability of the Maximum Likelihood Estimate. So let us stop this module here, we will continue with other aspects in subsequent modules. Thank you very much.
