Linear Minimum Mean Squared Error (LMMSE) Estimate Derivation - Part II

Hello, welcome to another module in this massive open online course on MMSE Estimation for Wireless Communication Systems. So, we are looking at the linear MMSE estimator that is the linear minimum mean square error estimator or also known as the LMMSE estimator and we are looking at finding the optimal weighting vector \bar{c} that is the combining vector \bar{c}

(Refer Slide Time: 00:48)

and we said that if you have a function f of \bar{c} function f of the vector \bar{c} , then the derivative with respect to \bar{c} that is this is a function of \bar{c} and it is derivative with respect to \bar{c} will be $\frac{dF}{dc_1} \frac{dF}{dc_2}$ so on $\frac{dF}{dc_N}$ that is derivative with respect to each components. So, naturally this is an n dimensional vector where n itself is the dimension of this vector \bar{c} for instance, let us take an example let us consider a simple scenario where this f of \bar{c} equals this function is k , this function of \bar{c} is k which is a constant.

Then dF , then dF in fact, this dF we can write here instead of dF , since we are considering the derivative this dF by $d\bar{c}$.

(Refer Slide Time: 02:11)

The image shows a whiteboard with handwritten mathematical content. At the top, the function is defined as $f(\vec{c}) = K \leftarrow \text{constant}$. Below this, the total derivative is expressed as $\frac{dF}{d\vec{c}} = \begin{bmatrix} \frac{\partial K}{\partial c_1} \\ \frac{\partial K}{\partial c_2} \\ \vdots \\ \frac{\partial K}{\partial c_N} \end{bmatrix}$. Red arrows point from each element in the vector to a zero, and the entire expression is equated to zero. Below this, the result is written as $\frac{dF}{d\vec{c}} = 0$.

So, I will write $d f$ by $d \vec{c}$ that will be d of that is that will be equal to let us write it over here your $d f$ by $d \vec{c}$ will be partial derivative of k with respect to c_1 derivative of k with respect to c_2 derivative of k with respect to c_N and each of these is equal to 0 since, this is a derivative of a constant with respect to $c_1 c_2 c_N$ therefore, each of these are equal to 0, this equal to 0 which means $d f$ by $d \vec{c}$ is equal to 0, the derivative of this function f if f is a constant. We already know this means very straight for the derivative of constant with respect to a scalar quantity is 0 and now we are naturally extending to a vector, we are saying that this derivative of this constant with respect to this vector is zero.

(Refer Slide Time: 03:40)

Let \bar{u} be a constant vector

$$\bar{u}^T \bar{c} = [u_1 \ u_2 \ \dots \ u_N] \begin{bmatrix} c_1 \\ c_2 \\ \vdots \\ c_N \end{bmatrix}$$
$$\bar{u}^T \bar{c} = u_1 c_1 + u_2 c_2 + \dots + u_N c_N$$
$$\frac{d \bar{u}^T \bar{c}}{d \bar{c}} = \begin{bmatrix} u_1 \\ u_2 \\ \vdots \\ u_N \end{bmatrix} = \bar{u}$$

Let us now consider a slightly more advanced scenario, slightly more complex scenario. Let us consider a vector in a product with a vector. So, let us say u is a constant vector, let \bar{u} be a constant vector, then the inner product is $\bar{u}^T \bar{c}$ which is the row vector $u_1 \ u_2 \ \dots \ u_N$ times the column vector $c_1 \ c_2 \ \dots \ c_N$ and this is equal to $u_1 c_1 + u_2 c_2 + \dots + u_N c_N$, we already said this \bar{u} is a constant vector. So, this is $\bar{u}^T \bar{c}$, hence the derivative of this quantity. Now, this $\bar{u}^T \bar{c}$ with respect to this quantity with respect to the vector \bar{c} .

Now, you can see this is nothing but the derivative of $\bar{u}^T \bar{c}$ with respect to c_1 , the derivative you can see is u_1 with respect to c_2 and the partial derivative will be $u_2 \ \dots$ with respect to c_N , the partial derivative is u_N .

(Refer Slide Time: 05:34)

$$\frac{d\bar{u}}{d\bar{c}} = \bar{u}$$
$$\bar{u}^T \bar{c} = \bar{c}^T \bar{u} = [c_1 \ c_2 \ \dots \ c_N] \begin{bmatrix} u_1 \\ u_2 \\ \vdots \\ u_N \end{bmatrix}$$
$$= c_1 u_1 + c_2 u_2 + \dots + c_N u_N$$

Therefore, this is equal to nothing but the vector \bar{u} . We have this interesting result that the derivative of $\bar{u}^T \bar{c}$ with respect to \bar{c} is \bar{u} , we have this result over here. The previous result we have is with respect to the constant that is the derivative of this constant. So, we have this derivative when this f of \bar{c} is the constant derivative with respect to \bar{c} that is equal to zero.

Now, of course you will also see this $\bar{u}^T \bar{c}$, this is also equals to $\bar{c}^T \bar{u}$ correct this is also equal to $\bar{c}^T \bar{u}$ which is basically your row vector $c_1 \ c_2 \ \dots \ c_N$ times to the column vector $u_1 \ u_2 \ \dots \ u_N$ and this is equal to $c_1 u_1 + c_2 u_2 + \dots + c_N u_N$. So, we have $\bar{u}^T \bar{c}$ is also the same thing as $\bar{c}^T \bar{u}$. In fact, these are both scalar quantity. So, they are equal to the transpose of each other and $\bar{c}^T \bar{u}$ is basically nothing but the transpose of $\bar{u}^T \bar{c}$.

(Refer Slide Time: 07:17)

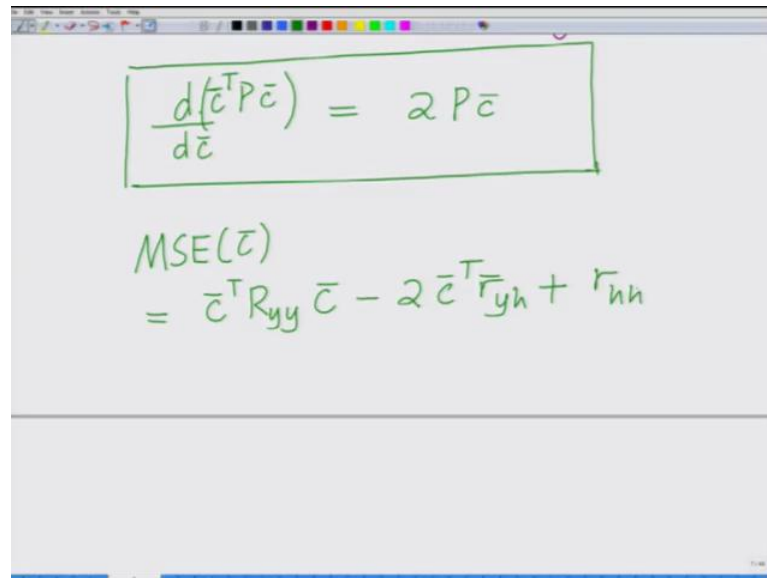

$$= c_1 u_1 + c_2 u_2 + \dots + c_N u_N$$
$$\boxed{\frac{d(\bar{c}^T \bar{u})}{d \bar{c}} = \frac{d \bar{u}^T \bar{c}}{d \bar{c}} = \bar{u}}$$

$\bar{c}^T P \bar{c}$ ← Quadratic Form
P = P^T matrix P is symmetric

And therefore if we take the derivative we have the derivative of c bar transpose u bar with respect to c bar will be equal to the derivative of u bar transpose c bar with respect to c bar and we already know this derivative of u bar transpose c bar with respect to c bar, this is equal to u bar. So, we have this principle.

Now, let us consider the second order derivative that is a quadratic function of c bar that is we have considered the constant, we have considered a linear function of c bar where it is waited by the combining vector u bar that is u 1 c 1 plus u 2 c 2 so on up to u N c N that is the u bar transpose c bar or c bar transpose u bar. Let us now look at a quadratic function of c bar that is function which involves squares of the terms of this vector, squares of the components of this vector c bar and that function is basically your c bar transpose p c bar, this is known as a quadratic form and further we are considering interesting scenario where p is equal to p transpose that is matrix p is symmetric. Further, we are considering a scenario where this matrix p is symmetric that is p is equal to p transpose and in this scenario it can be shown that the derivative of c bar transpose p c bar with respect to c bar, this is equal to twice p c bar.

(Refer Slide Time: 09:04)

The image shows a whiteboard with two mathematical equations written in green. The first equation is enclosed in a green rectangular box and reads: $\frac{d(\bar{c}^T P \bar{c})}{d\bar{c}} = 2P\bar{c}$. Below this, the second equation reads: $MSE(\bar{c}) = \bar{c}^T R_{yy} \bar{c} - 2\bar{c}^T r_{yh} + r_{hh}$.

This can be shown alright we will not be show this explicitly over here. The derivative of this quadratic form, the derivative of $\bar{c}^T P \bar{c}$ with respect to \bar{c} is equal to twice the matrix P into \bar{c} where this matrix P is a symmetric matrix that is P is equal to P transpose. Now, we have all the basic results related to the vector derivative, derivative of this function of this vector \bar{c} with respect to \bar{c} . Let us now go back to our MSE the mean square error cost function, as a function of this vector \bar{c} combining vector \bar{c} differentiate it, set it equal to zero to find the optimal vector \bar{c} which minimizes the mean squared error that will give us the MMSE estimate. This is linear in nature that is the linear MMSE estimate or the LMMSE estimate. Now, if you look at our MSE as a function of \bar{c} recall we already derived this previously, the MSE as a function of \bar{c} , this is equal to your $\bar{c}^T R_{yy} \bar{c}$ minus twice $\bar{c}^T r_{yh}$ plus r_{hh} .

(Refer Slide Time: 10:46)

$$\begin{aligned}
 \frac{d \text{MSE}(\bar{c})}{d \bar{c}} &= \frac{d}{d \bar{c}} \left(\underbrace{\bar{c}^T R_{yy} \bar{c}}_{\bar{c}^T P \bar{c}} - 2 \underbrace{\bar{c}^T \bar{r}_{yh}}_{\bar{c}^T \bar{u}} + \underbrace{r_{hh}}_k \right) \\
 &= 2 R_{yy} \bar{c} - 2 \bar{r}_{yh} + 0 \\
 \frac{d \text{MSE}}{d \bar{c}} &= \frac{2 R_{yy} \bar{c} - 2 \bar{r}_{yh}}{\text{Derivative of MSE w.r.t } \bar{c}}
 \end{aligned}$$

Now, we have to differentiate this MSE which is a function of \bar{c} with respect to the vector \bar{c} . So, this is a vector derivative or also basically known as a gradient and this is equal to the derivative with respect to \bar{c} of $\bar{c}^T R_{yy} \bar{c}$ minus twice $\bar{c}^T \bar{r}_{yh}$ plus r_{hh} . Now, you can see this will be equal to now look at this, this is of the form $\bar{c}^T P \bar{c}$. So, its derivative will be twice, P here is the matrix R_{yy} , so it will be twice the matrix R_{yy} times \bar{c} minus this is of the form $\bar{c}^T \bar{u}$. So, its derivative will be $2 \bar{c}^T \bar{u}$ derivative is \bar{u} that is \bar{r}_{yh} and r_{hh} , this is a constant k . So, derivative of this with respect of \bar{c} equals zero. This derivative with respect to \bar{c} of the MMSE is twice $R_{yy} \bar{c}$ minus twice \bar{r}_{yh} , this is the derivative of the MSE with respect to \bar{c} . $d \text{MSE}$ with respect to $d \bar{c}$.

Now, remember to find the optimal \bar{c} , I have to equate this derivative to zero. So, now, set this derivative to zero to find that \bar{c} which minimized the MMSE that will give us the MMSE the minimum mean square error.

(Refer Slide Time: 13:08)

$$\begin{aligned} & \Rightarrow 2R_{yy} \bar{c} - 2\bar{r}_{yh} = 0 \\ & \Rightarrow R_{yy} \bar{c} = \bar{r}_{yh} \quad \bar{r}_{yh} = E\{\bar{y}h\} \\ & \Rightarrow \boxed{\bar{c} = R_{yy}^{-1} \bar{r}_{yh}} \end{aligned}$$

Minimizes MSE. (MMSE).
 $E\{\bar{y}\bar{y}^T\} = R_{yy}$

So, set equal to zero to find \bar{c} which minimizes the MSE, this basically implies that your quantity, the derivative $2 r_{yy} \bar{c} - 2 \bar{r}_{yh}$ is equal to 0, this implies that $r_{yy} \bar{c}$ equals \bar{r}_{yh} , this implies \bar{c} equals, this is the system of linear equation. Therefore, \bar{c} equals $r_{yy}^{-1} \bar{r}_{yh}$. So, this is now the vector which minimizes the MMSE that is the yields the minimum mean square error correct and this is the combining vector \bar{c} that is \bar{c} equals $r_{yy}^{-1} \bar{r}_{yh}$, that is the expression now we have finally derived for the combining which remember what is \bar{c} ? \bar{c} is nothing but contains the coefficients $c_1 c_2 \dots c_N$ such that if you form $c_1 y_1 + c_2 y_2$ so on up to $c_1 c_N y_N$, that yields the linear estimate which minimizes the mean squared error.

Also to recall what is r_{yy} , just recall briefly in case it is not already clear r_{yy} equals expected $\bar{y} \bar{y}^T$ and this \bar{r}_{yh} is the cross co-variance that is expected \bar{y} into h that is the cross co-variance between the observation vector \bar{y} and the parameter h .

(Refer Slide Time: 15:53)

Handwritten derivation on a whiteboard showing the LMMSE estimate. At the top, it states $E\{\bar{y}\bar{y}^T\} = R_{yy}$. Below, the estimate \hat{h} is expressed as a linear combination of observations: $\hat{h} = c_1 y_1 + c_2 y_2 + \dots + c_N y_N$. This is then written as $\bar{c}^T \bar{y}$. A note $(AB)^T = B^T A^T$ is written in pink. The expression is then written as $(R_{yy}^{-1} \bar{r}_{yh})^T \bar{y}$, and finally simplified to $\bar{r}_{yh}^T (R_{yy}^{-1})^T \bar{y}$. The term $\bar{r}_{yh}^T (R_{yy}^{-1})^T$ is highlighted in pink.

Now, what do we have? The optimal MMSE estimate \hat{h} this is $c_1 y_1$ plus $c_2 y_2$ plus so on $c_N y_N$, this is the LMMSE estimator, remember now we are in the LMMSE domain, this is the LMMSE which is equal to $\bar{c}^T \bar{y}$ and we have already derived the expression for \bar{c} , \bar{c} is $R_{yy}^{-1} \bar{r}_{yh}$, this transpose times \bar{y} which is equal to now look at this, this is a b transpose we will use the property that a b transpose equals b transpose a transpose to write this as $\bar{r}_{yh}^T R_{yy}^{-1}$ transpose into \bar{y} .

(Refer Slide Time: 17:06)

Handwritten derivation on a whiteboard showing the relationship between cross-correlation matrices. It starts with the expression $\bar{r}_{yh}^T (R_{yy}^{-1})^T \bar{y}$. Below, it defines $\bar{r}_{yh} = E\{\bar{y}h\}$ and $\bar{r}_{hy} = E\{h\bar{y}^T\}$. Then, it shows $(\bar{r}_{hy})^T = (E\{h\bar{y}^T\})^T = E\{\bar{y}h\} = \bar{r}_{yh}$. The final result $\bar{r}_{hy} = \bar{r}_{yh}^T$ is boxed.

Now, observe two things one is this $\bar{r}^T y$ is expected value of \bar{y} into h and $\bar{r}^T h$ is expected value of $h^T \bar{y}$ transpose and therefore, if you take the transpose of $\bar{r}^T h$, now if you look at this $\bar{r}^T h$ transpose that is equal to expected $h^T \bar{y}$ transpose which is equal to expected value of \bar{y} transpose into h because h is a scalar quantity, h transpose equal to h .

So, this is equal to $\bar{r}^T h$ this is equal to \bar{r}^T of course, this has to be $\bar{r}^T h$ $h^T \bar{y}$ value $h^T \bar{y}$. This will be \bar{y} into h . So, this will be \bar{r}^T into h . So, $\bar{r}^T h$ transpose is $\bar{r}^T y$ h which means $\bar{r}^T h$ is equal to $\bar{r}^T y$ h transpose. This is the relation between these two quantities they are transposes of each other $\bar{r}^T h$ is the transpose of $\bar{r}^T y$ h .

(Refer Slide Time: 18:47)

$$R_{yy} = E \{ \bar{y} \bar{y}^T \}$$

symmetric matrix

$$\Rightarrow R_{yy} = R_{yy}^T$$

$$\Rightarrow R_{yy}^{-1} = (R_{yy}^{-1})^T$$

Now, if you look at this quantity $\bar{r}^T y$ inverse transpose relies that $\bar{r}^T y$ equals expected $\bar{y}^T \bar{y}$ transpose, this is a symmetric quantity correct implies $\bar{r}^T y$ equals $\bar{r}^T y$ transpose since it is a symmetric and also naturally if the matrix is symmetric its inverse is also symmetric, this also implies $\bar{r}^T y$ inverse is $\bar{r}^T y$ inverse transpose and therefore, I can basically simplify this quantity here, first instead of $\bar{r}^T y$ transpose, I can use $\bar{r}^T h$ $\bar{r}^T y$ inverse transpose this is the same as $\bar{r}^T y$ inverse. So, I can write this as $\bar{r}^T y$ inverse \bar{y} and this is the expression for the LMMSE estimate and this is the succinct as well as very interesting expression.

(Refer Slide Time: 20:09)

$$\Rightarrow R_{yy} = R_{yy}^T$$
$$\Rightarrow R_{yy}^{-1} = (R_{yy}^{-1})^T$$

LMMSE Estimate is given as,

$$\hat{h} = \bar{r}_{hy} R_{yy}^{-1} \bar{y}$$

For h, \bar{y} jointly Gaussian, MMSE \equiv LMMSE.

Let me rewrite it again, the LMMSE estimate is finally derived as, the LMMSE estimate is given as \hat{h} equals \bar{r}_{hy} into R_{yy}^{-1} into \bar{y} , this is the expression for the LMMSE estimate and if you notice this, you will observe something very interesting, this looks exactly identical to the expression for the MMSE estimate that is minimum mean square error estimate, but realize something very important, this is not the MMSE estimate this is the LMMSE estimate, realize that the MMSE estimate was derived assuming that the observation \bar{y} and the parameter h are jointly Gaussian.

So, what this means is something very interesting if \bar{h} , \bar{y} and h are jointly Gaussian, then the MMSE and the LMMSE estimate are the same, otherwise this expression that is \bar{r}_{hy} times R_{yy}^{-1} into \bar{y} is only the LMMSE estimate that is it is only the optimal MMSE estimate in the class of linear estimators, but it is not the general MMSE estimate. The general MMSE estimate will still be given by the quantity expected value of h given \bar{y} , that is the expected value of the posterior probability density function which may be difficult to find, that is why we embarked upon this LMMSE.

So, the point to remember here is for Gaussian or for the scenario for h comma \bar{y} jointly Gaussian, your MMSE is identical to LMMSE.

(Refer Slide Time: 22:39)

However, For arbitrarily Distributed h, \bar{y} , this is only the LMMSE estimate. NOT MMSE.

MMSE of LMMSE Estimate:

$$MSE(\hat{z}) = \bar{c}^T R_{yy} \bar{c} - 2 \bar{c}^T F_{yh} + \frac{\sigma_h^2}{r_{hh}}$$

However, for arbitrarily distributed h and \bar{y} , this is only the LMMSE estimate. In fact, generally this will not be the MMSE estimate. So, generally speaking this will not be the MMSE estimate. So, I am just going to not the MMSE estimate. So, what you can see is if the joint probability density function of the observation vector \bar{y} and the parameter h is Gaussian, then this expression $r_{hh}^{-1} \bar{y}^T R_{yy}^{-1} \bar{y}$ is basically the MMSE estimate itself of course if the MMSE, then it is a MMSE and also it is linear.

So, it is naturally the LMMSE also, but however for arbitrarily distributed h and observation vector \bar{y} this is simply the LMMSE estimator that it is only the lowest, that is it is only the estimate which is the lowest mean square error or the minimum mean square error amongst the class of linear estimators, but it might not be because there might be other non-linear estimators which might have a lower MMSE which might deal a lower mean square error, but we are not interested in finding them because finding them is very complex.

So, we are settling for the best estimator amongst the class of linear estimators and we are calling it the LMMSE estimate or the linear minimum mean square error estimator. So, that is the important thing to keep in mind that is for this scenario where this h and \bar{y} are not jointly Gaussian since evaluation of the MMSE estimate is complex, we have evaluated a simplistic LMMSE estimator right which is basically the optimal

amongst the class of linear estimators alright. So, this is the expression for the LMMSE estimate which we are going to invoke again fairly of and an this an important result because the LMMSE estimate is widely used in both signal processing and communications and it is used in several applications in single processing and communications.

Now, let us also compute the resulting MMSE or MMSE of the LMMSE or MMSE of the LMMSE estimator and this can be derived as follows, again we have the MSE as a function of \bar{c} recall we already derived that MSE as a function of \bar{c} , this is $\bar{c}^T R_{yy} \bar{c} - 2 \bar{c}^T r_{yh} + r_{hh}$, this is nothing but σ_h^2 .

(Refer Slide Time: 26:23)

MMSE of LMMSE

$$MSE(\bar{c}) = \bar{c}^T R_{yy} \bar{c} - 2 \bar{c}^T r_{yh} + r_{hh}$$

substituting $\bar{c} = R_{yy}^{-1} r_{yh}$
 $\bar{c}^T = r_{yh}^T R_{yy}^{-1}$

$$= r_{yh}^T R_{yy}^{-1} R_{yy} R_{yy}^{-1} r_{yh} - 2 r_{yh}^T R_{yy}^{-1} r_{yh} + \sigma_h^2$$

$$= r_{yh}^T R_{yy}^{-1} r_{yh} - 2 r_{yh}^T R_{yy}^{-1} r_{yh} + \sigma_h^2$$

Now, I will substitute the expression for \bar{c} , substituting the expression for \bar{c} , remember \bar{c} equals $r_{yy}^{-1} r_{yh}$ and \bar{c}^T is equal to r_{yh}^T into r_{yy}^{-1} . So, we can substitute that expression here and therefore, this becomes well \bar{c}^T is r_{yh}^T into r_{yy}^{-1} into r_{yy} into r_{yy}^{-1} into r_{yh} minus twice \bar{c}^T that is minus twice r_{yh}^T into r_{yy}^{-1} into r_{yh} plus r_{hh} which is σ_h^2 and now you can see this r_{yy}^{-1} and r_{yy} cancels. So, we are left with $r_{yh}^T r_{yy}^{-1} r_{yh}$ minus twice again the same quantity you can see interestingly we have the same quantity $r_{yh}^T r_{yy}^{-1} r_{yh}$ plus σ_h^2 .

(Refer Slide Time: 28:11)

The image shows a whiteboard with handwritten mathematical derivations. At the top, there are some faint notes: $= r_{hy} R_{yy}^{-1} r_{yh} \sigma_h^2 - r_{hh}$. The main derivation is as follows:

$$= \boxed{\sigma_h^2 - r_{hy} R_{yy}^{-1} r_{yh}} \quad \text{MMSE of LMMSE}$$

$$= r_{hh} - r_{hy} R_{yy}^{-1} r_{yh}$$

$$r_{hh} = E\{h^2\}$$

$$r_{hy} = E\{h \bar{y}^T\} = r_{yh}^T$$

$$R_{yy} = E\{\bar{y} \bar{y}^T\}$$

Therefore, finally this gives the sigma h square minus r bar h y r y y inverse r bar y h and this is equal to the MMSE of minimum mean square error of the LMMSE estimator, this is the expression for the minimum mean square error that is your sigma h square and you can also right this as this is also equal to your r h h minus r bar h y r y y inverse r bar y h.

Let us just write the various quantities again your r h h is expected value of h into h that is h square r bar h y equals expected value of h y bar transpose which is r bar y h transpose and r y y equals expected value of y bar y bar transpose and these are the different quantities and this is the resulting minimum mean square error of the LMMSE estimate. Again you see that it has the same expression as that of the minimum mean squared error for the Gaussian and that is naturally the case because for the Gaussian the MMSE and the LMMSE are the same ok.

So, both the LMMSE estimator and the MMSE estimator yield the same mean squared error or the same minimum mean squared error. However, for a Non-Gaussian probability density function of h and the observation vector y bar, this is simply the MMSE minimum mean square error yield which is given by the linear MMSE estimate that is the estimator which is best amongst the class of linear estimator, the actual MMSE of an optimal MMSE estimator if that can be found that the MSE of that will naturally be lower than this because this is simply the linear MMSE estimate.

So, that is something to keep in mind alright and of course, here we have considered a simple scenario where all these quantities are zero mean it is so important to keep in mind that this basically is based on the assumption that all the quantities, the parameter h , the observation vector \bar{y} are basically zero mean alright and this can also be extended to scenarios where these are not necessary. So, that completes the derivation of the LMMSE estimator and we are going to look at applications of this LMMSE estimator in the subsequent modules.

Thank you very much.
