Lecture – 20

**Example of Linear Minimum Mean Squared Error (LMMSE)
Estimate for Multi-Antenna Downlink Wireless Channel**

Hello. Welcome to another module in this massive open online course on Bayesian MMSE Estimation for Wireless Communication Systems. So far we have looked at the MMSE estimate or even the LMMSE estimate for a non-Gaussian vector parameter \mathbf{h} , where \mathbf{h} is a vector parameter and we particularly illustrated this for the case of estimation of a multi-antenna downlink wireless channel. So, now to understand it better let us do a simple example to see how this vector channel estimate is computed.

(Refer Slide Time: 00:54)

So, in today's module we will be doing example for the multi-antenna downlink vector parameter channel estimation. Of course the motivation I say LMMSE you have to understand that if the parameter is Gaussian then it becomes MMSE, example for LMMSE estimation of multi-antenna downlink wireless channel, we would like to an example for this.

Consider towards this example consider a base station with M equal to 2 antennas, so we want to consider a base station with M is equal to 2 antennas. That means, the base station has 2 transmitted antennas. And of course as per the scenario we considering the user only have a single receive. Then later we will extend to this a scenario where the user also as the multiple antennas then it will become a MIMO channel; that is the multiple inputs multiple output wireless channel. So, right now we are considering only multiple and transmit antenna, so it is a MISO channel; multiple input single output channel.

(Refer Slide Time: 02:49)

$$y(k) = x_1(k)h_1 + x_2(k)h_2 + v(k)$$

Observation

channel coefficients

Noise

$$\bar{x}(k) = \begin{bmatrix} x_1(k) \\ x_2(k) \end{bmatrix}$$

Pilot Symbol Transmitted From TX 1

Pilot Symbol From TX 2.

So, the system module for this can be given as $y(k)$ which is the received symbol at time instant k equals $x_1(k)h_1 + x_2(k)h_2 + v(k)$; $v(k)$ is the noise, $y(k)$ is the observation. And we have h_1 and h_2 these are the two channel coefficients of the multi-antenna channel. Further, what we have is that our pilot vector $\bar{x}(k)$ this is equal to the pilot vector $\bar{x}(k)$ is equal to $[x_1(k) \ x_2(k)]$, where time instant k $x_1(k)$ is symbol transmitted from transmit antenna 1 from transmit antenna 1 and this is the pilot symbol in fact both are pilot symbols from transmit antenna is a pilot symbol from transmit antenna 2.

So, we have pilot symbol from transmit antenna 1 and pilot symbol. This is the pilot vector \bar{x} of k which consist of two pilot symbols; x_1 k from transmit antenna 1 x_2 k from transmit antenna 2.

(Refer Slide Time: 05:07)

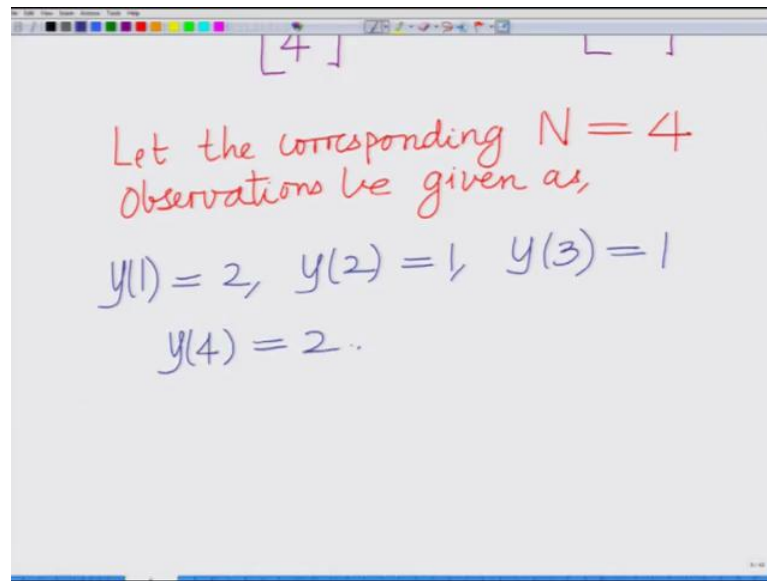

Pilot vector
Time k .
 $N = 4$ Pilot Vectors.

$$\bar{x}(1) = \begin{bmatrix} 5 \\ 4 \end{bmatrix}, \quad \bar{x}(2) = \begin{bmatrix} 4 \\ 5 \end{bmatrix}$$

$$\bar{x}(3) = \begin{bmatrix} 3 \\ 4 \end{bmatrix}, \quad \bar{x}(4) = \begin{bmatrix} 4 \\ 3 \end{bmatrix}$$

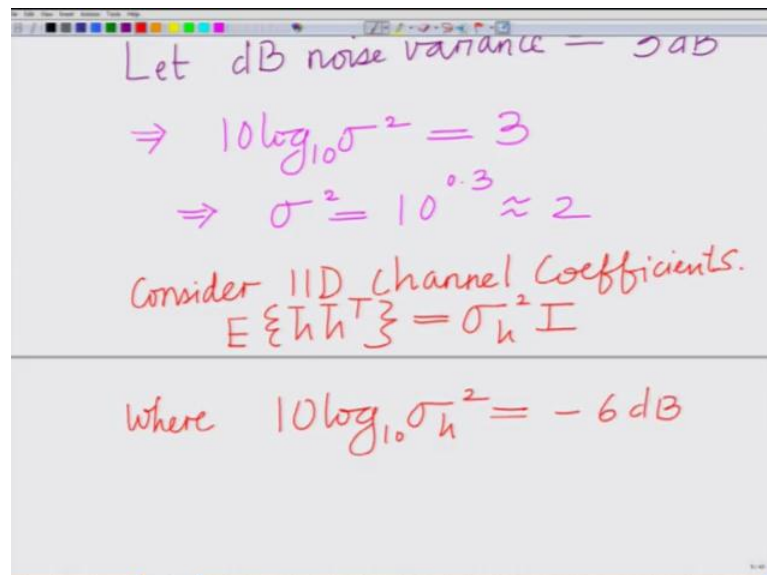

Now in this particular example, so each of this is a pilot vector at time k . Now let us consider four such pilot vectors. Consider in our example N equal to 4 pilot vectors, let us say the pilot vectors are x_1 bar equals 5 comma 4, 5 4 this is a first two pilot vector x_2 bar equals 4 5 x_3 bar equals 3 4 and x_4 bar equals 4 3. These are the 4 pilot vectors. And consider the observations then then corresponding to this we will have see where N equal to 4 pilot vectors corresponding to this we will have N equal to 4 observations.

(Refer Slide Time: 06:39)

So, let the corresponding N equal to 4 observations these be given as y_1 equals 2, y_2 equals 1, y_3 equals 1, y_4 equals 2.

(Refer Slide Time: 07:34)

Let the dB noise variance be equal to 3 dB, this implies that dB noise variance will basically \log_{10} of sigma square equals three which implies sigma square equals 10 to

the power of point 3 which is approximately equal to 2. We already done this several times that is 3 dB is approximately equal to 2. So, 10 to the power of 0.3 is approximately equal to 2, so 3 dB noise variance means noise variance is equal to 2.

And also we are considering IID channel coefficients, not necessarily Gaussian that is expected value of $\bar{h} \bar{h}^T$ is if you consider IID channel coefficients and the covariance matrix will be proportional to identity. So, expected value of $\bar{x} \bar{h} \bar{h}^T$ is equal to $\sigma_h^2 I$, where σ_h^2 in dB that is the average channel variance of the average channel gain in dB equals minus 6 dB.

(Refer Slide Time: 09:14)

The image shows a whiteboard with handwritten mathematical steps. At the top, it says "E Ch 13". The main derivation is as follows:

$$\text{Where } 10 \log_{10} \sigma_h^2 = -6 \text{ dB}$$

$$\Rightarrow \sigma_h^2 = 10^{-0.6}$$

$$= (10^{0.3})^{-2}$$

$$\approx (2)^{-2} = \frac{1}{4}$$

$$\sigma_h^2 = \frac{1}{4}$$

Now, what does this imply? This implies that σ_h^2 equals 10 to the power of minus 0.6 this is equal to 10 to the power of 0.3 whole raise to the I am writing this in terms of 10 to the power of minus 0.3, because we know 10 to the power of 0.3. This is 10 to the power of 0.3 is approximately to 2, so 10 to the power of 2 raise to the power of minus 2 this is equal to 1 over 4. So, σ_h^2 equals 6 dB in minus 6 dB implies σ_h^2 equals 1 over 4. So, that is what we have.

Now what we need to now, we need to compute the LMMSE estimate of the channel vector \bar{h} . Of course, I have said this many times if the channel vector \bar{h} is a

Gaussian channel vector then LMMSE estimate that is a linear minimum mean squared error estimate itself is the MMSE estimate is the minimum mean squared error estimate. Of course, if it is not Gaussian then it is simply the LMMSE estimate. This is the best among the class of linear estimates. This is the something to keep in mind I will keep repeating this frequently because it is a certain, but very important point.

(Refer Slide Time: 10:34)

We need to compute LMMSE Estimate of channel vector \hat{h}

2×1
 $M = 2$

$$X = \begin{bmatrix} \bar{x}^T(1) \\ \bar{x}^T(2) \\ \bar{x}^T(3) \\ \bar{x}^T(4) \end{bmatrix} = \begin{bmatrix} 5 & 4 \\ 4 & 5 \\ 3 & 4 \\ 4 & 3 \end{bmatrix}$$

Pilot Matrix
 $N \times M$
 $N = 4, M = 2$

So, we need to compute the LMMSE estimate of channel vector \hat{h} by the way this is $M \times 1$ channel vector which means it is 2×1 , since M is equal to 2; we have 2 antennas at the base station. Now for this first let us form the pilot matrix x which is equal to $\bar{x}^T(1)$ $\bar{x}^T(2)$ $\bar{x}^T(3)$ $\bar{x}^T(4)$, where $\bar{x}^T(1)$, $\bar{x}^T(2)$, $\bar{x}^T(3)$, $\bar{x}^T(4)$ are the 4 pilot vectors. So, this will simply be 5 4, 4 5, 3 4, 4 3 and this is a pilot matrix.

This is a pilot matrix which is remembered $N \times M$ that is N is equal to 4 and M is equal to 2. This is a $N \times M$ pilot matrix. So, now we have the pilot matrix. Remember this is your x which is the pilot matrix. This is the first important aspect of multi-antenna channel distribution we have to form the pilot matrix.

(Refer Slide Time: 12:34)

Observation vector,
 $\vec{y} = \begin{bmatrix} y(1) \\ y(2) \\ y(3) \\ y(4) \end{bmatrix} = \begin{bmatrix} 2 \\ 1 \\ 1 \\ 2 \end{bmatrix}$
 $N \times 1 = 4 \times 1$

Next we form the observation vector that is \vec{y} bar. Remember \vec{y} bar is N cross one where N is the number of observation. Next we form the observation vector \vec{y} bar equals y_1 y 2 y 3 coma y 4 which is basically your 2 1 1. And now this is your observation vector. So, observation vector is \vec{y} bar and \vec{y} bar is N cross 1 this is equal to 4 cross 1 observation vector.

(Refer Slide Time: 13:30)

Recall the LMMSE Estimate,
$$\hat{h} = (\sigma_h^2 \underbrace{X^T X}_{2 \times 2} + \sigma^2 I)^{-1} \sigma_h^2 X^T \vec{y}$$
$$= \left(X^T X + \frac{\sigma^2}{\sigma_h^2} I \right)^{-1} X^T \vec{y}$$
$$\hat{h} = \left(\frac{X^T X}{\sigma^2} + \frac{1}{\sigma_h^2} I \right)^{-1} \frac{X^T}{\sigma^2} \vec{y}$$

Now, recall the LMMSE estimate or MMSE estimate recall that to be more precise the LMMSE estimate; linear minimum mean squared error. Recall that this is given as \hat{h} which is the LMMSE estimate equals, we derived this in the previous module $\sigma^2 \mathbf{h}^T (\mathbf{X}^T \mathbf{X} + \sigma^2 \mathbf{I})^{-1} \mathbf{X}^T \mathbf{y}$. Now remember again once again we point out the previous module that this is much more simpler version that is computing $\mathbf{X}^T \mathbf{X}$ that $\sigma^2 \mathbf{h}^T \mathbf{X}^T \mathbf{X} + \sigma^2 \mathbf{I}$ inverse because look at this \mathbf{X} is 4 cross 2 therefore $\mathbf{X}^T \mathbf{X}$ will be 2 cross 2 matrix; this is a 2 cross 2 matrix.

So, inversion of these 2 cross 2 matrix is much simpler, but if you are considering $\mathbf{X} \mathbf{X}^T$ that is other version other formulation based on $\mathbf{X} \mathbf{X}^T$ then that will be a 4 cross 4 matrix. So, we have to compute the inverse of 4 cross 4 matrix which is much more complicated compared to this which is much more simpler.

Now I will proceed, basically now of course one can also now notice that I can also simplify this slightly by bringing out this σ^2 . I can write this also as first let us bring out σ^2 , so $\mathbf{X}^T \mathbf{X} + \sigma^2 \mathbf{I}$ by σ^2 $\mathbf{h}^T \mathbf{X}^T \mathbf{X} + \sigma^2 \mathbf{I}$ inverse, of course when σ^2 comes out it is comes in the denominator that cancels with σ^2 so this becomes $\mathbf{X}^T \mathbf{y}$. And now bring out σ^2 so this becomes $\mathbf{X}^T \mathbf{X} + \sigma^2 \mathbf{I}$ inverse into $\mathbf{X}^T \mathbf{y}$ or slightly more convenient to use this formulation.

(Refer Slide Time: 15:55)

$(\sigma^2, \sigma_h^2) / \sigma^2 = 0$
Let us compute

$$X^T X = \begin{bmatrix} 5 & 4 & 3 & 4 \\ 4 & 5 & 4 & 3 \end{bmatrix} \begin{bmatrix} 5 & 4 \\ 4 & 5 \\ 3 & 4 \\ 4 & 3 \end{bmatrix}$$

Now, let us compute this matrix. So, let us compute this matrix x transpose x divided by σ^2 plus σ^2 over σ^2 $I_{2 \times 2}$ inverse. So, now towards this first let us start by computing x transpose x ; we now x that is the pilot matrix so x transpose x simply take the transpose of x . So, this is 5 4, 4 5, 3 4, 4 3; 5 4, 4 5, 3 4, 4 3 is transpose of the matrix into itself you can compute this. This is your x transpose this is your x .

(Refer Slide Time: 16:48)

$X^T X = \begin{bmatrix} 66 & 64 \\ 64 & 66 \end{bmatrix}$ $X = \begin{bmatrix} 1 & 0 \\ 4 & 3 \end{bmatrix}$

$$\frac{1}{\sigma^2} X^T X + \frac{1}{\sigma_h^2} I_{2 \times 2}$$
$$= \frac{1}{2} \begin{bmatrix} 66 & 64 \\ 64 & 66 \end{bmatrix} + \frac{1}{4} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix}$$

And this will become basically your 66 you can compute this $66, 64, 64, 66$ is a symmetric matrix. Of course $x^T x$ is symmetric matrix transpose of this matrix is equal to itself and naturally you can say that is a symmetric matrix, it is a symmetric 2×2 cross matrix.

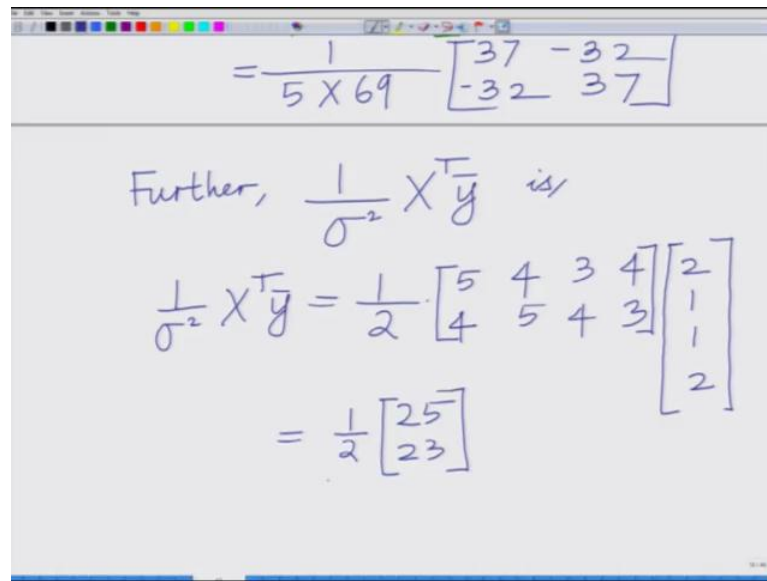

Now, let us compute this quantity $\frac{1}{\sigma^2} x^T x + \frac{1}{\sigma^2} I$ this becomes half $66, 64$ into $64, 66$ plus $\frac{1}{\sigma^2} I$; σ^2 is 1 by 4 , so $\frac{1}{\sigma^2} I$ is $\frac{1}{4}$ times identity $1 \ 0 \ 0 \ 1$. Of course, this is the 2×2 identity matrix that is the $N \times M$ identity matrix which will be equal too.

(Refer Slide Time: 17:59)

$$\begin{aligned}
 & \frac{1}{2} \begin{bmatrix} 64 & 66 \\ 66 & 64 \end{bmatrix} + \frac{1}{4} \begin{bmatrix} 1 & 0 \\ 0 & 1 \end{bmatrix} \\
 &= \begin{bmatrix} 33 & 32 \\ 32 & 33 \end{bmatrix} + \begin{bmatrix} 4 & 0 \\ 0 & 4 \end{bmatrix} \\
 &= \begin{bmatrix} 37 & 32 \\ 32 & 37 \end{bmatrix} \\
 (X^T X)^{-1} &= \frac{1}{37^2 - 32^2} \begin{bmatrix} 37 & -32 \\ -32 & 37 \end{bmatrix} \\
 &= \frac{1}{5 \times 69} \begin{bmatrix} 37 & -32 \\ -32 & 37 \end{bmatrix}
 \end{aligned}$$

Now you can compute this thing, this will be $33 \ 32, 32 \ 33$ half of $x^T x$ plus $\frac{1}{4}$ times identity matrix is $4 \ 0 \ 0 \ 4$, this will be equal to $37 \ 32, 32 \ 37$. And now we can say we can complete the inverse of this matrix easily. The inverse of this matrix is $\frac{1}{\det}$ since this is the 2×2 matrix that is $\frac{1}{37^2 - 32^2}$ that is $37^2 - 32^2$ times switch the diagonal elements $37 \ 37$, because both are same negative of the off diagonal elements -32 comma -32 . At this will becomes $\frac{1}{37^2 - 32^2}$ is $37 - 32$ that is 5 times 37 plus 32 that is 69 times of course $37 - 32 - 32 \ 37$.

(Refer Slide Time: 19:25)

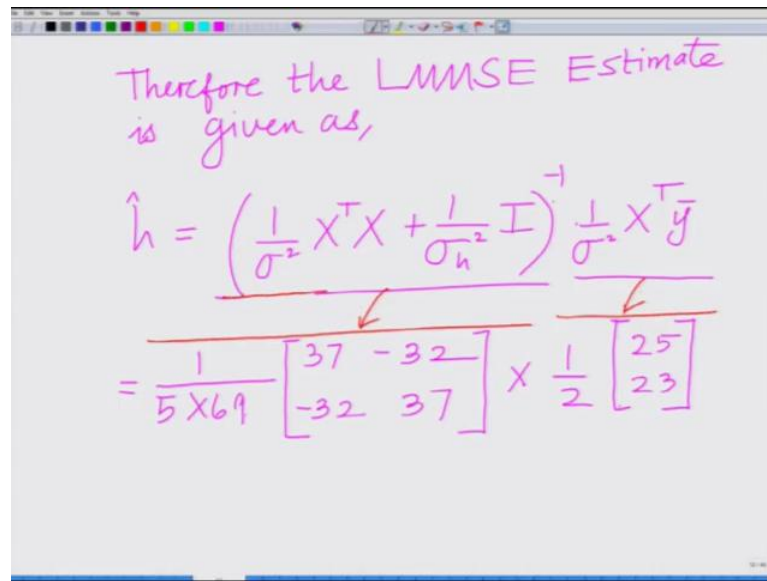

$$= \frac{1}{5 \times 69} \begin{bmatrix} 37 & -32 \\ -32 & 37 \end{bmatrix}$$

Further, $\frac{1}{\sigma^2} X^T \bar{y}$ is,

$$\frac{1}{\sigma^2} X^T \bar{y} = \frac{1}{2} \begin{bmatrix} 5 & 4 & 3 & 4 \\ 4 & 5 & 4 & 3 \end{bmatrix} \begin{bmatrix} 2 \\ 1 \\ 1 \\ 2 \end{bmatrix}$$
$$= \frac{1}{2} \begin{bmatrix} 25 \\ 23 \end{bmatrix}$$

Now, let us compute this other quantity $\frac{1}{\sigma^2} X^T \bar{y}$. Further, $\frac{1}{\sigma^2} X^T \bar{y}$ is what this is, this is $\frac{1}{\sigma^2}$ times $X^T \bar{y}$; so σ^2 is 2 so $\frac{1}{\sigma^2} X^T \bar{y}$ is $\frac{1}{2} X^T \bar{y}$; so $\frac{1}{2} X^T \bar{y}$ is $\frac{1}{2} \begin{bmatrix} 5 & 4 & 3 & 4 \\ 4 & 5 & 4 & 3 \end{bmatrix} \begin{bmatrix} 2 \\ 1 \\ 1 \\ 2 \end{bmatrix}$ which is equal to $\frac{1}{2} \begin{bmatrix} 25 \\ 23 \end{bmatrix}$. And therefore we have computed these both components $\frac{1}{\sigma^2} X^T \bar{y}$ and the other. So, now we put both these things together to compute the final LMMSE estimate.

(Refer Slide Time: 20:33)

Therefore the LMMSE Estimate is given as,

$$\hat{h} = \left(\frac{1}{\sigma^2} X^T X + \frac{1}{\sigma_h^2} I \right)^{-1} \frac{1}{\sigma^2} X^T \bar{y}$$
$$= \frac{1}{5 \times 69} \begin{bmatrix} 37 & -32 \\ -32 & 37 \end{bmatrix} \times \frac{1}{2} \begin{bmatrix} 25 \\ 23 \end{bmatrix}$$

Therefore, the LMMSE estimate is given as \hat{h} is equal to the first part is $\frac{1}{\sigma^2} X^T X + \frac{1}{\sigma_h^2} I$ inverse into $\frac{1}{\sigma^2} X^T \bar{y}$. We have computed both these quantities above this will be basically your $\frac{1}{5 \times 69}$ into $\begin{bmatrix} 37 & -32 \\ -32 & 37 \end{bmatrix}$ times this quantity; that is $\frac{1}{\sigma^2} X^T \bar{y}$ that is half we have over here $\begin{bmatrix} 25 \\ 23 \end{bmatrix}$ that is a column vector 25. It should be clear to you that this is basically $\frac{1}{\sigma^2} X^T \bar{y}$, and this quantity is basically this $\frac{1}{\sigma^2} X^T X + \frac{1}{\sigma_h^2} I$ inverse.

(Refer Slide Time: 22:15)

$$= \frac{1}{690} \begin{bmatrix} 125+64 \\ 115-64 \end{bmatrix} = \frac{1}{690} \begin{bmatrix} 189 \\ 51 \end{bmatrix}$$
$$\hat{h} = \begin{bmatrix} \frac{189}{690} \\ \frac{51}{690} \end{bmatrix} = \begin{bmatrix} \frac{63}{230} \\ \frac{17}{230} \end{bmatrix}$$

Now you multiply these two things together and what you are going to get is basically 1 over 690 times and you can check this 125 plus 64 115 minus 64 equals 1 over 690 times, well this becomes 189 comma 115 minus 64 that is 51.

So, your \hat{h} is basically if you write it explicitly 99 divided by 690 and the second component is 51 divided by 690 and taking three common both the numerator and denominator of each component what we have is 63 divided by 230 and 17 over 230.

(Refer Slide Time: 23:35)

$$\hat{h} = \begin{bmatrix} 63/230 \\ 17/230 \end{bmatrix}$$

LMMSE Estimate of channel vector \bar{h}

$$\begin{bmatrix} \hat{h}_1 \\ \hat{h}_2 \end{bmatrix} = \begin{bmatrix} 63/230 \\ 17/230 \end{bmatrix}$$

And therefore, what we have is net in LMMSE estimate \hat{h} equals let us this write this down 63 divided by 230 17 divided by 230. And slightly more complicated to compute than the simple least squares estimate people will realize because of the complicated nature of the expression for the LMMSE estimates. So, this is basically your LMMSE estimate of your channel LMMSE estimate of the channel vector \bar{h} . Therefore, now if you look at this \hat{h} is basically estimate with channel vector \bar{h} itself is a channel vector corresponding to two transmit antennas therefore it has two components. So, \hat{h} is basically of the form \hat{h}_1 \hat{h}_2 which is estimate of channel coefficient 1 and \hat{h}_2 which is estimate of channel coefficient 2, so this is 63 by 230 and 17 by 230 which implies.

(Refer Slide Time: 25:02)

LMMSE Estimate of channel vector \hat{h}

$$\begin{bmatrix} \hat{h}_1 \\ \hat{h}_2 \end{bmatrix} = \begin{bmatrix} \frac{63}{230} \\ \frac{17}{230} \end{bmatrix}$$

Estimate of channel coefficient h_1 $\Rightarrow \hat{h}_1 = \frac{63}{230}$

Estimate of channel coefficient h_2 $\Rightarrow \hat{h}_2 = \frac{17}{230}$

Basically now if you just write it explicitly again although all of these are very clear from the example just to write this a little more explicitly this 63 by 230 and \hat{h}_2 equals 17 by 230. What is the \hat{h}_1 estimate of h_1 that is channel coefficient 1 estimate of channel coefficient h_1 , and what is \hat{h}_2 this is your estimate of channel coefficient h_2 ; this is estimate of channel coefficient of h_2 . So, this completes our example for the LMMSE estimate of the vector parameter which is a multi-antenna channel vector for the downlink.

So, what we have done in this we have consider simple example for multi-antenna downlink channel estimation with M equal to 2 antennas, N equal to 4 pilot vectors, consider the pilot matrix, the observation vector illustrated how to compute the LMMSE estimate. We have derived the LMMSE estimate from which the channel vector which one can extract naturally the LMMSE estimates of the individual channel coefficients.

So, we will stop with this and continues with the other aspects in the subsequent modules.

Thank you.
