**Sequences of Random Variable (contd.)**

(Refer Slide Time: 00:36)

So, now we have been discussing this issue of random sequences.

(Refer Slide Time: 00:53)

That is just for a recap. We initially started with just one random variable and function of one random variable. Then, two random variables, then one function involvement two random variables and two functions involvement two random variables. Here, we try to generalize that to a set of  $n$  random variables which are ordered as sequences  $x_1, x_2$  up to  $x_n$ , and we first consider one function of such  $n$  random variables, and then  $n$  functions of such  $n$  random variables, right.

So, there were several issues which we did not discuss last time. They are all you know just analogous to those issues which we considered in the case of two random variables. So, we will just continue from where we left last time, but just one remark. We have so long used to real value random variables, but random variables could be complex valued also. Now, suppose we have got this.

(Refer Slide Time: 01:52)

Handwritten notes on a whiteboard:

complex valued random variable.

$$z_1 = x_1 + jy_1$$

$$\vdots$$

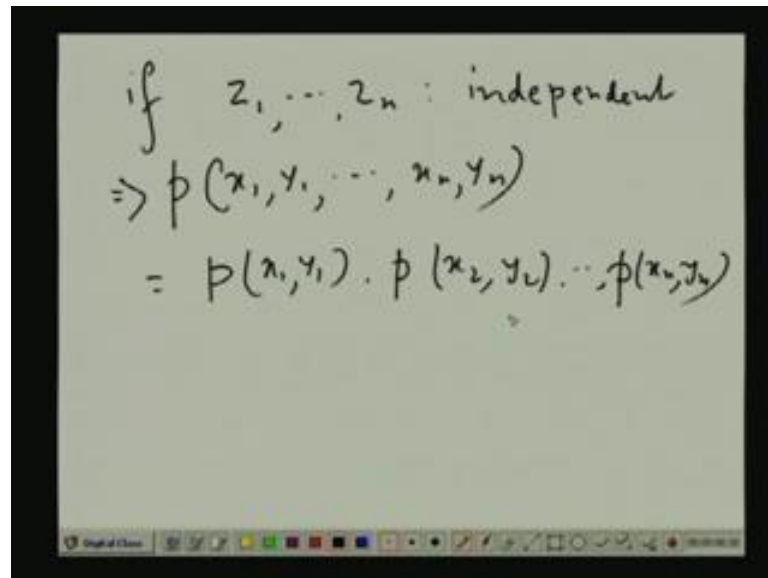

$$z_n = x_n + jy_n$$

prob. density  $f(z_1, \dots, z_n)$   
 $= f(x_1, y_1, x_2, y_2, \dots, x_n, y_n)$

Suppose  $z_1$  is  $x_1$  plus  $jy_1$  dot dot dot up to say  $z_n$   $x_n$  plus  $jy_n$ . So,  $z_1$  to  $z_n$ , we have got set of  $n$  complex random variables, but remember each of these,  $z_1$  to  $z_n$ , they have got two components. One is a real component and another is an imaginary component  $x_1$   $y_1$  and now,  $x_1$  also is random variable,  $y_1$  also is random variable. Similarly,  $x_2$  is random variable;  $y_2$  is random variable. So, a set of  $n$  complex random variable equivalent being is a set of twice  $n$  real value random variables which means probability

density of  $z_n$  is same as actually a probability density function of  $2n$  variables  $x_1, y_1, x_2, y_2, \dots, x_n, y_n$ .

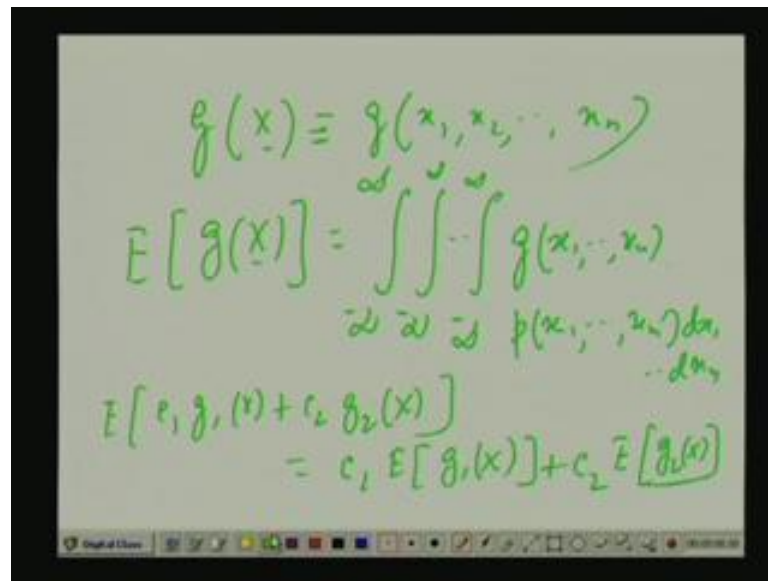

(Refer Slide Time: 03:19)

if  $z_1, \dots, z_n$  : independent  
 $\Rightarrow p(x_1, y_1, \dots, x_n, y_n)$   
 $= p(x_1, y_1) \cdot p(x_2, y_2) \cdot \dots \cdot p(x_n, y_n)$

Further, if  $z_1, \dots, z_n$ , they are independent, then it means that  $p(x_1, y_1, \dots, x_n, y_n)$  that will be like this which stands for probability density for  $z_1$ , because  $z_1$  has the two random variables, real value random variables  $x_1, y_1$  in it, then  $p(x_2, y_2, \dots, x_n, y_n)$ .

(Refer Slide Time: 04:10)

The image shows a whiteboard with handwritten mathematical formulas in green ink. The first line defines a function  $g(x) \equiv g(x_1, x_2, \dots, x_n)$ . The second line shows the expected value  $E[g(x)] = \int \dots \int g(x_1, \dots, x_n) p(x_1, \dots, x_n) dx_1 \dots dx_n$ . The third line shows the linearity property:  $E[c_1 g_1(x) + c_2 g_2(x)] = c_1 E[g_1(x)] + c_2 E[g_2(x)]$ . At the bottom of the whiteboard, there is a toolbar with various icons for editing and presentation.

Suppose we have got single function  $g(x)$ .  $X$  is a vector. Basically  $x$  means actually is a function of  $n$  random variables, say  $x_1, x_2, \dots, x_n$ . Now, by extending our previous argument, we can then say that expected value of  $g(x)$  is nothing but times the corresponding probability density function  $dx_1 \dots dx_n$ . Obviously, if instead of these real variables  $x_1, x_2, \dots, x_n$ , we are a set of complex  $n$  number of complex valued random variables  $z_1, z_2, \dots, z_n$ .

Then, instead of having  $n$  fold multiple integral, you would have had twice  $n$  fold multiple integral, and there probability density function would have been I mean this is  $g(z_1, \dots, z_n)$ , and probability density function as we proved have been  $p(z_1, \dots, z_n)$  and we would have a  $dz_1 \dots dz_n$ . Just that generalization also as before you can see that there is a linearity that is valued here. Also, that is expected value of say sum of functions  $c_1 g_1(x) + c_2 g_2(x)$  is same as  $c_1 E[g_1(x)] + c_2 E[g_2(x)]$ . So, the linearity works.

(Refer Slide Time: 06:27)

Given a set of complex valued random variables:  $x_1, x_2, \dots, x_n$

$\Rightarrow E[x_k] = \mu_k$

$\Rightarrow$  covariance between  $x_i$  &  $x_j$

$C_{ij} = E[(x_i - \mu_i)(x_j - \mu_j)^*]$

$\Rightarrow$  variance of  $x_i = \sigma_i^2 = E[|(x_i - \mu_i)|^2]$

Given a set of complex valued in general, because now I wanted to be more general. So, complex valued random variables say  $x_1$  instead of  $z_1$ , I am calling them  $x_1$ . Now,  $x_1$   $x_2$   $\dots$   $x_n$ , then covariance we now define first say  $E$  of  $x_1$  say is  $\mu_1$  or  $E$  of  $x_k$  is  $\mu_k$ , where  $k$  goes from 1, 2 up to  $n$ , that is  $x_1$  as a mean value  $\mu_1$ ,  $x_2$  as a mean value  $\mu_2$  dot dot dot  $x_n$  has a  $\mu_n$  value  $\mu_n$ , and then we define covariance between say  $x_i$  and  $x_j$  as expected value. You can call it, sorry you can call it  $c_{ij}$ . This is expected value of  $x_i$  minus  $\mu_i$  times.

Now, the difference  $x_j$  minus  $\mu_j$  and a complex conjugation here. Earlier we have dealt with similar things, but since that time we were dealing with only real value complex variables. We have more simplified expression for this covariance, where there was no complex conjugation, but the more general case, this is the definition of covariance. Why this complex conjugate is necessary? Simple because if now you are interested in the variance of say  $x_i$ , say in variance of  $x_i$ , now we all know that variance denotes power expected value of the power that is average power. So, average power has to be real and non-negative.

So, if you put a star here, that will make the variance that is expected power real. How? You can easily see variance of  $x_i$  equal to say  $\sigma_i^2$  is what expected value of  $x_i$  minus  $\mu_i$  times again  $x_i$  minus  $\mu_i$  star which makes it this because complex number and its own conjugate multiplied gives rise to the mod square, and as mod square means it is real function, right. It is happening, because of this star. So, this is a variance, this is a

covariance. As before this covariance expression, you can simplify like before I repeat again here.

(Refer Slide Time: 10:32)

$$\begin{aligned}
 C_{ij} &= E[(x_i - \mu_i)(x_j - \mu_j)^*] \\
 &= E[x_i x_j^*] - \mu_i E[x_j^*] \\
 &\quad - \mu_j^* E[x_i] + \mu_i \mu_j^*
 \end{aligned}$$

$$\begin{aligned}
 x_j^* &= g(x_j) \Rightarrow E[x_j^*] = E[g(x_j)] \\
 &= \int_{-\infty}^{\infty} g(x_j) p(x_j) dx_j \\
 &= \left[ \int_{-\infty}^{\infty} x_j p(x_j) dx_j \right]^* = \mu_j^*
 \end{aligned}$$

Our  $c_{ij}$  was I am just repeating. You can now bring it up one term is  $E[x_i x_j^*]$ . Then, minus  $\mu_i E[x_j^*]$  if this cross term  $x_j^* - \mu_j^*$  minus  $\mu_j^* E[x_i]$  plus  $\mu_i \mu_j^*$ . Now, you see you have got a quantity like expected value of  $x_j$  conjugate. What is that? Now, we know that you can write  $x_j$  conjugate as a function of  $x_j$  given  $x_j$ , this function evaluate its conjugate. So,  $x_j^*$  is conjugate is a function of  $x_j$  which means this simple expected value of  $x_j^*$  is nothing but expected value of  $g(x_j)$ , and we have already seen this is nothing but  $g(x_j)$  times  $p(x_j) dx_j$ , right and there is an integral  $g(x_j)$ . It is a star. I replace this by  $x_j^*$ .  $p(x_j)$  is a real quantity.

So, you can also write this like minus infinity infinity  $x_j p(x_j) dx_j$ , and then star. That is first you replace  $g(x_j)$  by  $x_j^*$ , but you see that other quantity that is  $p(x_j)$  and  $dx_j$ , they are real valued. So, you can take the integral first, and then conjugate. What is this integral? This is nothing but expected value of  $x_j$  that is  $\mu_j$ . That is  $\mu_j^*$ . So, I will use this fact here.

(Refer Slide Time: 13:22)

$$\begin{aligned} \Rightarrow \text{if } x_i \text{ and } x_j \text{ are uncorrelated} \\ c_{ij} = 0 \Rightarrow E[x_i x_j^*] \\ = E[x_i] E[x_j^*] \\ = E[x_i x_j^*] - \mu_i \mu_j^* - \mu_i \mu_j^* \\ = E[x_i x_j^*] - E[x_i] E[x_j^*] \end{aligned}$$

So, I continue this as before  $E[x_i x_j^*]$ . In fact, this is called the correlation minus  $\mu_i$ , and you have seen while back, this is  $\mu_j^*$ , and then minus  $\mu_j^* \mu_i$  plus again  $\mu_i \mu_j^*$ . So, essentially it becomes  $E$  of  $x_i x_j^*$  minus. After simplification we only have  $1 \mu_i \mu_j^*$  which means  $E[x_i]$  which is  $\mu_i$  and  $E[x_j^*]$  which is  $\mu_j^*$  which means this implies if  $x_i$  and  $x_j$  are uncorrelated, then as before  $c_{ij}$  is equal to 0 meaning  $E[x_i x_j^*]$  is simple  $E[x_i] E[x_j^*]$ . Either you can take  $x_j^*$ , and then expected value of it or  $E$  of  $x_j$ , then conjugate. Either it is same. As an example, suppose you have got, one more thing. If  $x_1$  to  $x_n$ , there are statistically independent, then obviously  $p$  of  $x_1$  dot dot dot  $x_n$  is nothing but  $p$  of  $x_1$  into  $p$  of  $x_2$  into  $p$  dot dot dot  $p_{xn}$ , right.

(Refer Slide Time: 15:58)

$$X = X_1 + X_2 + \dots + X_n$$
$$E[X_n] = \mu_n$$
$$E[(X_n - \mu_n)^2] = \sigma_n^2$$

Also,  $X_1, \dots, X_n$ : independent

$$c_{ij} = E[(X_i - \mu_i)(X_j - \mu_j)^*]$$

Now, suppose we are given this that  $X$  is  $E$  of  $x_k$  is  $\mu_k$  and variance  $E$  of  $x_k$  minus  $\mu_k$  mod square is  $\sigma_k$  square. Then, firstly also  $x_1$  to  $x_k$ , they are independent. We all know and it is easily seen here that if two random variables are independent, they are also uncorrelated. Then, the covariance will be 0. For instance, if you just have doubt about it, where see that suppose say  $x_i x_j$  as before  $x_i$  minus  $\mu_i$   $x_j$  minus  $\mu_j$  star expected value, these are covariance. I am saying that if  $x_i$  and  $x_j$ , they are statically independent, then they are uncorrelated. That means the covariance will be 0. That is easily seen here. After all if you take the expected value of this, that means, you take this quantity as a function of two random variable  $x_i$  and  $x_j$ .

So, to find the expected value, you have to multiply by its joints probability in this function  $p$  of  $x_i x_j$ , but since  $x_i$  and  $x_j$  are statically independent, you can write  $p$  of  $x_i x_j$  as  $p_{x_i}$  into  $p_{x_j}$  and then integrate. So, one integral will be with respect to this  $x_i$  minus  $\mu_i$  multiplied by  $p$  of  $x_i$  integrated. That will be give rise to 0 because  $x_i$  as a mean  $\mu_i$ . Similarly, the other integrals also give rise to 0. So, if they are statically independent, the correlation is covariance is 0 and we said that they are uncorrelated. So, we have given here the fact that  $x_1$  to  $x_n$ , they are  $n$  number of mutually; I mean they are  $n$  number of mutually independent random variables which means they are uncorrelated also.

(Refer Slide Time: 18:28)

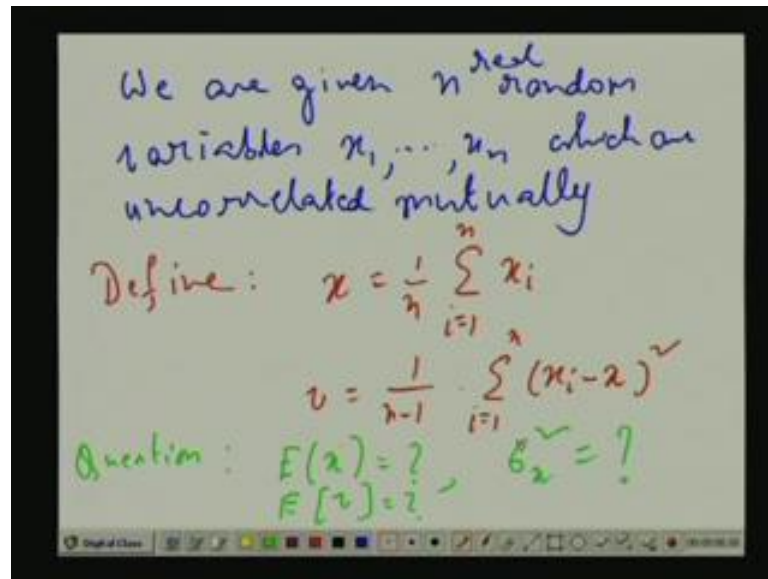

$$\begin{aligned}
 E[(x - \mu_n)^2] &= E[(x_1 - \mu_1) + \dots + (x_n - \mu_n)]^2 \\
 &= E\left[\left[ (x_1 - \mu_1) + \dots + (x_n - \mu_n) \right] \left[ (x_1 - \mu_1) + \dots + (x_n - \mu_n) \right]^x\right] \\
 &= \sigma_1^2 + \sigma_2^2 + \dots + \sigma_n^2
 \end{aligned}$$
  

$$\begin{aligned}
 E[x] &= \mu_1 + \mu_2 + \dots + \mu_n = \mu_n \\
 E[x - \mu_n] &= 0
 \end{aligned}$$

So, then what happens to  $E$  of  $x$ ? Obviously,  $E$  of  $x_1$  plus  $E$  of  $x_2$  dot dot dot  $E$  of  $x_n$  using the linearity. So, it is nothing but  $\sigma_1$ , sorry  $\mu_1$  plus  $\mu_2$  plus dot dot dot  $\mu_n$ . How about the variance  $E$  of this? I say  $\mu_x$ . How about  $\text{mod } x$  minus  $\mu_x$  square? As you know  $x$  is  $x_1$  plus  $x_2$  plus dot dot dot  $x_n$  which means we can write  $I$  replace  $x$  by  $x_1$  plus  $x_2$  plus dot dot dot  $x_n$   $\mu_x$  also by  $\mu_1$  plus  $\mu_2$  plus dot dot dot  $\mu_n$ . Then, that means, you can write it as simple here. First  $x$  minus  $\mu_1$  plus dot dot dot  $x$  minus  $\mu_n$  and on the other side,  $x$  minus again  $\mu_1$  plus dot dot dot dot  $x$  minus  $\mu_n$ , but star.

This is  $x$ , sorry this is  $x_1$  to  $x_n$   $x_1$  to  $x_n$ . That is I am replacing  $x$  by  $x_1$  plus  $x_2$  plus dot dot dot  $x_n$   $\mu_x$  by  $\mu_1$  plus  $\mu_2$  dot dot dot  $\mu_n$ . So, taking  $x_1$  with  $\mu_1$   $x_2$   $\mu_2$   $x_n$  with  $\mu_n$ . Now, if you take the product, the cross products are 0 because the variables  $x_1$  to  $x_n$ , they are given to be statistically independent which means they are uncorrelated. So, the covariance is 0. Only the direct products that is  $x_1$  minus  $\mu_1$  primes  $x_1$  minus  $\mu_1$  star expected value only, that is non-zero and that gives a variance of  $x_1$ . Similarly, the other one gives variance of  $x_2$ . So, that means this gives rise to what variance of  $x_n$   $x_1$ , that is  $\sigma_1$  square, then  $\sigma_2$  square plus dot dot dot  $\sigma_n$  square. We now consider a very interesting example which uses these concepts.

(Refer Slide Time: 21:52)

Suppose we are given means as before  $x$   $n$  which you can say uncorrelated mutually, then define that is simple sample average of this  $n$  random variable. Just add them and divide by the total number of variables involved that is  $n$ , and this is new random variable call it is  $\bar{x}$ . Similarly, define random variable say  $v$  as  $1$  by  $n$  minus  $1$  times  $x_i$  minus, this  $\bar{x}$  square.

Question is what is  $E(\bar{x})$  equal to what? Then, what is the variance? Just a minute. What is  $\sigma_{\bar{x}}$ ? May be instead of  $\bar{x}$ , it is better to remove the tilde just because there is no  $x$  anywhere. So, I remove  $\bar{x}$ . So,  $x$  is the sample average.  $X$  is an average of those  $n$  random variables  $x_1$  to  $x_n$ , and  $v$  is  $1$  by  $n$  minus  $1$  times this summation  $x_i$  minus that average  $\bar{x}$  average random variable. Mind you  $\bar{x}$  also is random variable. So,  $x_i$  minus  $\bar{x}$  whole square, and we are assuming, I forgot to mention that all the variables are real here. They are all real variables that is  $n$  real random variable.

So, question is what is  $E$  of  $\bar{x}$ ? That is this new random variable  $\bar{x}$  which is formed by averaging the  $n$  random variables. What is the expected value? That is the mean value or expected value of  $\bar{x}$ . Then, what is its variance?  $\sigma_{\bar{x}}^2$ , sorry equal to what and the other one what is the expected value of this. What is  $E(v)$ ? I am not interested in squaring it up because then these terms will be rest to the power  $4$  and it is not of use to me here. So, just what is the expected value of  $E(v)$ ? It is some sort of average square, square of what deviation of  $x_i$  from the average random variable.

Just take that, square it up, add for all the variables and divide instead by n here, I am dividing by n minus 1. So, that is the difference. So, it is not exact averaging. Exact averaging would have meant division by n, but here I am purposefully dividing by n minus 1. So, these two things you have to find out.

(Refer Slide Time: 27:07)

$$E[x] = \frac{1}{n} \sum_{i=1}^n E[x_i] = \mu$$

[Given:  $E[x_i] = \mu$ ,  $E[(x_i - \mu)^2] = \sigma^2$ ]

Define:  $x = \frac{1}{n} \sum_{i=1}^n x_i$

$$v = \frac{1}{n-1} \sum_{i=1}^n (x_i - x)^2$$

Question:  $E[x] = ?$ ,  $E[v] = ?$ ,  $\sigma_x^2 = ?$

First one is very simple. E of x using the linearity. Obviously, 1 by n summation E of xi. So, E of xi, what is E of xi? I forgot to mention that given for all random variables, they have the same mean mu, and same variance for all of them. Since they are real value, I am not putting any mod. So, sigma square is given. I forgot to mention this that we are given a set of n uncorrelated, that is mutually uncorrelated real valued random variables x 1 to x n, where each of them has same mean constant mean mu and constant variance sigma square. So, that is same for all the random variables.

Then, by just adding, and then averaging I found a new random variable. My question is what average value for that expected value of that. Then, each random variable is I found the difference between that. Each random variable with the average, what tilde square sum and average not exactly because that would have mean dividing by n. I am dividing by n minus 1. Then, we found this v. What is the expected value of v? That is the question. So, you first start with expected value of this x which obvious is in the linearity, and this formula expected value of x will be 1 by n summation. I can put the

expectation operator inside the summation and E of xi for all i is equal to mu. So, mu times n n n cancel. So, this will be equal to mu. So, x as the same average same expected value as each of the random variables has. Then question is what the variance of x is?

(Refer Slide Time: 30:04)

$$\begin{aligned}
 E[(x - \mu)^2] &= E\left[\frac{1}{n^2}(\sum x_i - n\mu)^2\right] \\
 &= \frac{1}{n^2} E\left[\{(x_1 - \mu) + (x_2 - \mu) + \dots + (x_n - \mu)\}^2\right] \\
 &= \frac{n \cdot \sigma^2}{n^2} = \frac{\sigma^2}{n}
 \end{aligned}$$

That means, that is now we have to find out what is this quantity. Mean value of x mu, we have already seen. So, what is this quantity? Now, what is x? We know that x is 1 by n summation xi i equal to 1 to n, right and now we replace this x here. So, that means, you can write it like this. E of you can take 1 by n square summation xi within bracket minus n times mu whole square. Very simple, we replace x by this. Why? We want to take 1 by n outside the brackets. So, it becomes 1 by n square. So, mu gets multiplied by n which means you can take 1 by n square outside because it is not random expected value of again xi minus mu. Sorry you have to put it this way.

X 1 minus mu plus x 2 minus mu plus dot dot dot x n minus mu whole square. In the whole square, the cross terms will be 0 as before because of uncorrelatedness. So, this will give rise to just variances for each of them and each of them as a same variance sigma square. So, there will be total n times sigma square. So, n into sigma square will come on the top n square here. So, you get sigma square by n. So, our second question is answered.

(Refer Slide Time: 32:47)

$$\begin{aligned}
 E[v] &= \frac{1}{n-1} \sum_{i=1}^n E[(x_i - \bar{x})^2] \\
 &= \frac{1}{n-1} \sum_{i=1}^n E\left\{[(x_i - \mu) - (\bar{x} - \mu)]^2\right\} \\
 &\Rightarrow E[(x_i - \mu)(\bar{x} - \mu)] \\
 &= \frac{1}{n} E\left\{(x_i - \mu) \left\{ (x_1 - \mu) + \dots + (x_n - \mu) \right\}\right\} \\
 &= \frac{\sigma^2}{n}
 \end{aligned}$$

Now, the third question is so that I rewrite again. We formed the variable  $v$ . Question is what is equal to what? For that we already know that mean of  $x_i$  is  $\mu$  mean of  $x$  is  $\mu$ . We first consider this thing  $E$  of what is this  $x_i$  minus  $\mu$ . That is the covariance between  $x_i$  and  $\bar{x}$ ,  $x_i$  minus  $\mu$  and  $\bar{x}$  minus  $\mu$  because  $x_i$  also as mean  $\mu$   $\bar{x}$  also as mean  $\mu$ . So, the covariance between any  $x_i$  and  $\bar{x}$ , what is that? Let us find it out.

Now, as before we replace  $\bar{x}$  by its expression, so  $1$  by  $n$  summation  $x_i$  minus  $\mu$   $1$  by  $n$  comes out and you can write this as  $x_1$  minus  $\mu$  plus dot dot dot dot  $x_n$  minus  $\mu$ . Once again all the terms will be  $0$  expected for the case, where from here I have got  $x_i$  minus  $\mu$ . So, only square of that will remain other terms like  $x_i$  minus  $\mu$  times  $x_1$  minus  $\mu$ . Expected value will be  $0$  because  $x_1$  and  $x_i$ , they are uncorrelated and likewise. Only when we have got a term  $x_i$  minus  $\mu$  from here, so square of that will come up expected value which is nothing but the variance for  $x_i$ , and variance of  $x_i$  we all know is a constant independent of  $i$  which is  $\sigma^2$ , right.

So, this will become nothing but  $\sigma^2/n$ . So, we now come to this question. What is  $E[v]$ ? So, if we apply  $E$  here using linearity, we will have this and you can write here  $1$  by  $n-1$  and same summation  $i$  equal to  $1$  to  $n$   $E$ , but inner quantity you can write like this square. Now, here there will one term  $x_i$  minus whole square expected value which will give  $\sigma^2$  to variance of  $x_i$  which is  $\sigma^2$  you know. Similarly,

another term will have expected value of  $x$  minus  $\mu$  whole square which is the variance of  $x$ , and we have already seen variance of  $x$  also be square by  $n$ , and there is a cross term twice expected value  $x_i$  minus  $\mu$   $x$  minus  $\mu$ . There is covariance between  $x_i$  and  $x$  which is also  $\sigma^2$  by  $n$ . We have just now seen.

(Refer Slide Time: 36:57)

$$\begin{aligned}
 E[s^2] &= \frac{1}{n-1} \sum_{i=1}^n E[(x_i - \bar{x})^2] \\
 &= \frac{1}{n-1} \sum_{i=1}^n E\left\{[(x_i - \mu) - (x - \mu)]^2\right\} \\
 &= \frac{1}{n-1} \left[ \sum_{i=1}^n \sigma^2 - \frac{2\sigma^2}{n} + \frac{\sigma^2}{n} \right] \\
 &= \frac{1}{n-1} \cdot n \cdot \sigma^2 \left[ \frac{n-1}{n} \right] = \sigma^2
 \end{aligned}$$

So, if we use those figures here, first is  $\sigma^2$ , then minus twice  $\sigma^2$  by  $n$  from the covariance term, the cross term, and then from the variance of the other one  $\sigma^2$  by  $n$ , and this  $\sigma^2$ . Now, we are summing that is a summation, right. Then, that is the summation of  $n$ . So, that means now what is it? If you take  $\sigma^2$  common, this is  $n$  times  $\sigma^2$ . If you take common  $\sigma^2$  by  $n$  minus twice  $\sigma^2$  root by  $n$ , so you are left only minus  $\sigma^2$  by  $n$  taking this  $\sigma^2$  common. So, you get  $n-1$  by  $n$  and this  $n$ , this  $n$  cancels. You are left with just  $\sigma^2$ . This is answer. Few definitions when the two random, when the random say  $x_1$  to  $x_n$ , they are independent. We have seen they are uncorrelated. Obviously, same applies for the complex random variables also.

(Refer Slide Time: 38:40)

$$\left. \begin{aligned} z_1 &= x_1 + jy_1 \\ z_2 &= x_2 + jy_2 \end{aligned} \right\}$$

if  $z_1, z_2$  : independent

$$\Rightarrow p(x_1, y_1, x_2, y_2) = p(x_1, y_1) \cdot p(x_2, y_2)$$
$$E[z_1 z_2^*] = \iint z_1 p(x_1, y_1) dx_1 dy_1 \cdot \iint z_2^* p(x_2, y_2) dx_2 dy_2$$

For instance, if say  $z_1$  is  $x_1 + jy_1$ ,  $z_2$  is say  $x_2 + jy_2$  and we say that  $z_1$  and  $z_2$ , they are statistically independent. That means that if  $z_1, z_2$  are independent, this will imply that probability density  $z_1, z_2$  which is nothing but some  $p_{x_1, y_1, x_2, y_2}$  will be same as  $x_1, y_1$  which goes for  $z_1$  times  $p_{x_2, y_2}$ , and if this is given, then for complex variables also complex random variable also, they will be uncorrelated. That is  $E$  of  $z_1, z_2^*$  will be  $E z_1$  into  $z_2^*$ . That is very easily seen, that is  $E$  of  $z_1 z_2^*$  will be nothing but  $z_1 z_2^*$  multiplied by the joint density integrated, but joint density can be written like this. It can be broken like this. So, there will be one on one side, we have got  $z_1$  times  $p_{x_1, y_1} dx_1 dy_1$ , and again  $z_2^* p_{x_2, y_2} dx_2 dy_2$ . Obviously, this will give rise to  $E z_1$  and this will give rise to  $E z_2^*$ . So, that means I write separately here.

(Refer Slide Time: 40:28)

$$E[z_1 z_2^*] = E[z_1] E[z_2^*]$$

Suppose,  $x_1, \dots, x_n$ : independent

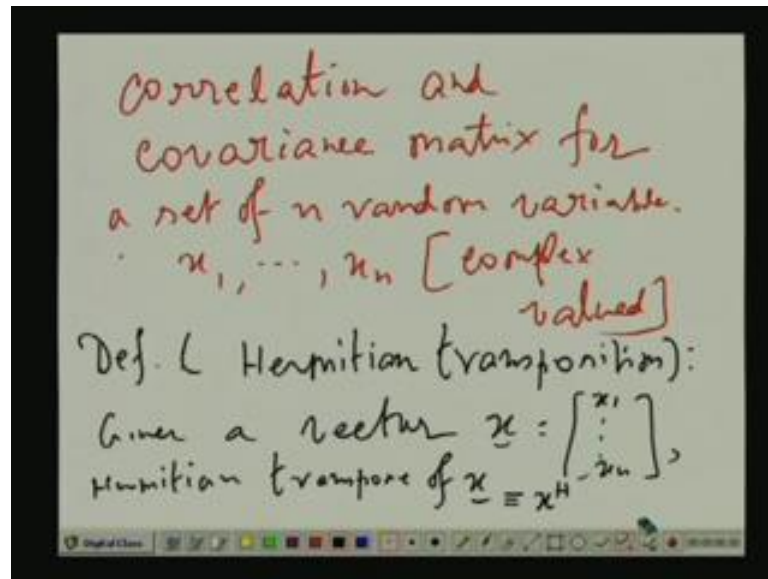

$$\Rightarrow E[g_1(x_1) g_2(x_2) \dots g_n(x_n)]$$
$$= E[g_1(x_1)] \cdot E[g_2(x_2)] \dots E[g_n(x_n)]$$

Here we see easily. Finally, suppose sorry suppose are independent. That means if you take instead of  $x_1$ , a function  $g_1$  instead of  $x_2$ , a function  $g_2$  dot dot dot a function  $g_n$  is same as after all. This whole product is again another function you calculate  $g_1$  sorry. You can write  $g_2$   $g_n$  different function.  $x_1$  as a function I mean I take a function  $g_1$  which works on  $x_1$ . Then, a function  $g_2$  which works on  $x_2$   $g_n$  works on  $x_n$ , and I consider the products which is basically a function  $g$  of  $x_1 x_2 x_n$ . Expected value will be what this product multiplied by the joint density integrated, but if they are independent, joint density is nothing but product of individual and marginal densities.

So, you just separate out the integral one with respect to  $x_1$ . Thus,  $g_1 x_1$  times probability density of  $x_1$  integrated same for  $x_2$  same for  $x_n$ . So, this will give rise to first one. Integral give rise to the expected value of that is  $g_1 x_1$ , then expected value of  $g_2 x_2$  dot dot dot expected value of  $g_n x_n$ . Now, I come to a very important topic that is correlation matrix and covariance matrix for a set of  $n$  random variables in general complex value to random variables in general complex valued.

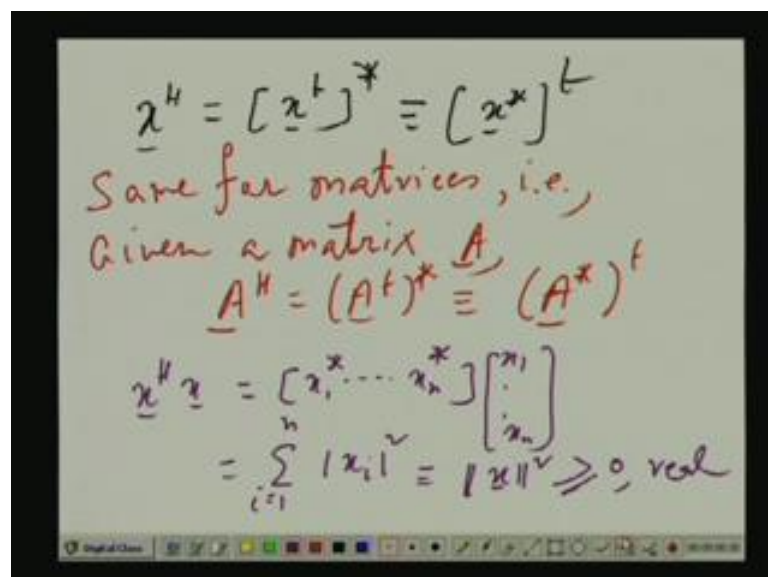

(Refer Slide Time: 43:18)

I need to define you know certain things like what is meant by hermitian transposition, definition of hermitian transposition given a vector  $x$  as say  $x_1$  dot dot dot  $x_n$  hermitian transpose which we denote by  $x$  hermitian. This will be given by actually by conjugate transpose. You have to transpose the vector, and then conjugate all the elements. It is not ordinary transposition. Ordinary transposition means just transpose the elements row vector becomes column vector or column vector becomes row vector likewise, but here we have to do one more step, that is conjugate the elements also.

(Refer Slide Time: 45:53)

So,  $x^H$  is nothing but you can either write  $x$  transpose. So, if it is a column vector, it becomes a row vector and vice versa, and then complex conjugation or equivalently first conjugate and transpose is called hermitian transpose, and is denoted by  $x^H$ . Similarly, for matrixes, same for matrixes, that is given a matrix  $A$ .  $A^H$  is nothing but either  $A$  transpose. Then, conjugate restrict the matrix transpose. You get another matrix. Then, conjugate all the elements or equally you first conjugate all the elements, and then transpose either we will get the same thing. Also, my notations if any symbol, any letter as a bar or underscore, then it is either a vector or a matrix.

Now, if it is written using capital letter, then it is a matrix. If it is written using lower case letter, then it is a vector, but both have an underscore that difference differentiates it or differentiates from scalars. One more thing you will see  $x$  hermitian  $x$ , this will what  $X$  is a column vector. So, it becomes a row vector transposition, and then conjugates it, and this is original  $x$ . So, basically it means mod of  $x_1$  square, then mod of  $x_2$  square dot dot dot mod  $x_n$  square, all that which is also called non square of the vector, and this is always greater than equal to 0 and real.

(Refer Slide Time: 48:44)

$$x^H x = \begin{bmatrix} x_1 \\ \vdots \\ x_n \end{bmatrix} [x_1^* \dots x_n^*]$$

$$= \begin{bmatrix} |x_1|^2 & x_1 x_2^* & \dots & x_1 x_n^* \\ x_2 x_1^* & |x_2|^2 & \dots & \dots \\ \vdots & \vdots & \ddots & \vdots \\ x_n x_1^* & \dots & \dots & |x_n|^2 \end{bmatrix}$$

$A$ : Hermitian matrix  
 if  $A^H = A$   
 $\begin{bmatrix} A_{11} & A_{12} & \dots & A_{1n} \\ A_{12}^* & A_{22} & \dots & \dots \\ \vdots & \vdots & \ddots & \vdots \\ \vdots & \dots & \dots & \vdots \end{bmatrix}$

On the other hand how about  $x x^H$ ? This will not become a scalar. Previous  $x^H x$  was a scalar number because  $x^H$  was a row vector,  $x$  was column vector. So, product was a scalar, but now here we have  $x$  as a row column vector as before  $x_1$  dot dot  $x_n$  and

obviously,  $x^H$  will be first is transpose which is row vector, and then conjugate it. So,  $x$   $1 \times n$  star dot dot dot  $x$   $n \times 1$  star which means we have trans like this. Mod  $x$   $1 \times 1$  square, then  $x$   $1 \times 1$  star  $x$   $2 \times 1$  star dot dot dot  $x$ . Sorry I make a mistake  $x$   $1 \times 2$  star. Then,  $x$   $1 \times n$  star, then again  $x$   $2 \times 1$  star, and then mod  $x$   $2 \times 2$  square likewise.

You see the first row and second column element is  $x$   $1 \times 2$  star and second row first column element is there conjugate of this  $x$   $2 \times 1$  star, and this works. This matrix actually is called a hermitian matrix which means if you have trans like say  $A$   $1 \times 1$   $A$   $1 \times 2$  dot dot dot say  $A$   $1 \times n$ . If I transpose it,  $A$   $1 \times 2$  comes here, and then conjugate. So, this place will be  $A$   $1 \times 2$  star. This remains  $A$   $2 \times 2$  and likewise. Now, this matrixes are hermitian matrixes, but before that you see one thing.

(Refer Slide Time: 51:36)

$$\begin{aligned}
 (\underline{A} \ \underline{B})^H &= (\underline{B})^H (\underline{A})^H \\
 \Rightarrow \left[ (\underline{A} \ \underline{B})^t \right]^* & \\
 &= \left[ \underline{B}^t \ \underline{A}^t \right]^* \\
 &= \left[ (\underline{B}^t)^* \ (\underline{A}^t)^* \right] \\
 &= \underline{B}^H \ \underline{A}^H
 \end{aligned}$$

$A$   $B$  hermitian is  $B$  hermitian  $A$  hermitian. This is not difficult to see after all  $AB$  hermitian means you take  $AB$  transpose conjugate, and  $AB$  transpose is  $B$  transpose  $A$  transpose conjugate and conjugate of products means product of the conjugate. You have to take the conjugate on each of them, right. So, that means,  $B$  transpose conjugate  $A$  transpose conjugate which is nothing but  $B$  hermitian  $A$  hermitian.

(Refer Slide Time: 52:27)

$$\begin{aligned} \underline{A} &= \underline{x} \underline{x}^H \\ \underline{A}^H &= (\underline{x} \underline{x}^H)^H \\ &= (\underline{x}^H)^H (\underline{x})^H \\ &= \underline{x} \underline{x}^H = \underline{A} \end{aligned}$$

Now, previously I considered a matrix of this form. You can call it  $A$ . My claim is this is a hermitian matrix, that is  $A$ , and its hermitian transpose, they are same. Hermitian transpose means I mean you take the transpose. So,  $i, j$  th element where  $i$  is the row,  $j$  is the column on transposition that goes to the  $j, i$  th position, and then you conjugate that also. So, after hermitian transposition  $j, i$  th position gets filled by the  $ij$  th element of the previous matrix with the conjugate, that is a hermitian transposition. So, you get back the same matrix, and then we call it hermitian matrix.

Now, you can see one thing. This hermitian because what is  $A^H$ , what is the transposition  $H$ , right and  $AB$  hermitian means hermitian  $\times$  hermitian, right. You can see hermitian of a hermitian transpose. That gives you the original vector. After all this was a column vector by hermitian transposition. I mean in a row vector with conjugate, I mean elements conjugated. Again taking the hermitian transpose, so it again becomes a column vector and conjugation disappears. So, you get back  $x$  and here as before  $x^H$  which is the original vector matrix  $A$ . So, a matrix which on hermitian transposition gives you back itself, then it is a hermitian matrix.

(Refer Slide Time: 54:33)

$$A = \begin{pmatrix} A_{11} & A_{12} & A_{13} \\ A_{21} & A_{22} & A_{23} \\ A_{31} & A_{32} & A_{33} \end{pmatrix}$$

$$A^H = \begin{pmatrix} A_{11}^* & A_{21}^* & A_{31}^* \\ A_{12}^* & A_{22}^* & A_{32}^* \\ A_{13}^* & A_{23}^* & A_{33}^* \end{pmatrix}$$

$(A^H)_{ij} = (A_{ji})^*$   
 $(A^H)_{21} = (A_{12})^*$   
 $(A^H)_{31} = (A_{13})^*$   
 $(A^H)_{ii} = (A_{ii})^* = A_{ii}$

That is suppose you take  $A_{11}$ ,  $A_{12}$ ,  $A_{13}$ ,  $A_{21}$ ,  $A_{22}$ ,  $A_{23}$ ,  $A_{31}$ ,  $A_{32}$ ,  $A_{33}$ , and then what is  $A^H$  transposition will not change the diagonal elements.  $A_{11}$  remains in  $A_{11}$  only. Thing is that they get conjugated. Hermitian transposition means  $A_{12}$  comes here with a conjugate, and  $A_{21}$  goes here with a conjugate,  $A_{31}$  comes here with a conjugate,  $A_{13}$  comes here with a conjugate,  $A_{23}$  comes here with a conjugate,  $A_{32}$  comes here with a conjugate. Like these two matrixes are same, then  $A$  will be called a hermitian matrix. That means firstly, the diagonally elements  $A_{11}$  must be  $A_{11}^*$  which means it must be real valued element.

So, the diagonal similarly for  $A_{22}$ , similarly for  $A_{33}$ . So, for a hermitian matrix diagonal entries are real and other entries are conjugate symmetric of each other, like 21 th element of  $A^H$ , that is second row first column. This is nothing but 12 th element of  $A$  that is 21 th of  $A^H$  is same as 12 th star of  $A$ . So, 21 th element is this and 12 th element of  $A$  is this. If you put a star here, you get back this element. That means  $A^H$  this matrix it is  $ij$  th element is nothing but  $A$  matrix. It is  $ji$  th element star. That is a hermitian transposition.

Now, if  $A$  and  $A^H$  are same, that means,  $A_{21}$  and that is we should have  $A_{21}$  is equal to  $A_{21}^*$  should be just a conjugate of this  $A_{12}^*$ .  $A_{31}$  should be  $A_{13}^*$  star because this and this are to be same and likewise. So, the transmission of the hermitian matrix  $ij$  th element. That means I think I continue from here in the next class because some more

properties are to be discussed because this hermitian matrices, they give rise to what is called the correlation and covariance matrices. So, that is all for today. We will continue from here in the next class because time is up.

Thank you very much.

(Refer Slide Time: 57:34)

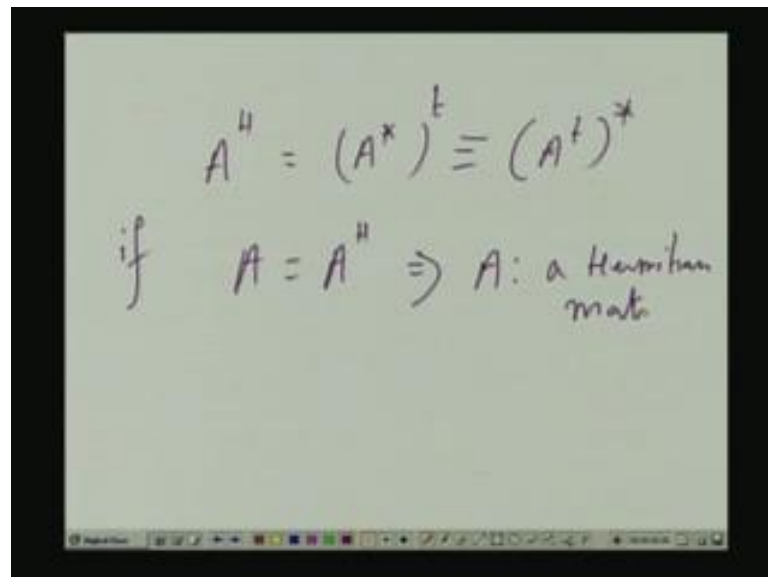

(Refer Slide Time: 57:39)

So, in the last class, we were discussing these correlation matrices and in that connection I talked about what is called hermitian matrices and hermitian transposition and things like that. So, today we will continue from there.

(Refer Slide Time: 58:06)

$$A^H = (A^*)^t \equiv (A^t)^*$$

if  $A = A^H \Rightarrow A$ : a Hermitian matrix

So, just to recall what we did last time given a matrix say  $A$ , we define a hermitian transposition that is  $A^H$  which actually is nothing but  $A$  conjugate that is complex. Take the complex conjugate of each entry of  $A$  and their transpose which is also equivalent to doing in the other way. First take the transposition of  $A$ , and then a complex conjugate. That is very simple. So, if  $A$  is not a matrix, but just a vector, say column vector, then its hermitian transposition is what we first transpose. So, it becomes a row vector, and then takes the conjugate of each element. Similarly, if  $A$  is a row vector, there hermitian transposition will be a column vector with all the original elements are complex conjugated. So, it happens if  $A$  is a hermitian, and then  $A$  is called a hermitian matrix.
