Lecture – 21
Characterization of Signals and Systems (Contd.)

Welcome to the lectures on Modern Digital Communication Techniques. In the previous lecture we have seen the relationship between the output of band pass channel when excited by the band pass signal. And that relationship is straightforward for us because it is the outcome of a channel whose impulse response is given by $h(t)$. That is what we have defined.

(Refer Slide Time: 00:43)

CC BY
IIT KGP

$$\mathcal{F}\{h(t)\} = \mathcal{F}\left[h_2(t)e^{j2\pi f_c t} + h_2^* e^{-j2\pi f_c t} \right]$$

$$h(t) = h_2(t)e^{j2\pi f_c t} + h_2^* e^{-j2\pi f_c t}$$

$$h(t) = 2 \operatorname{Re} \left[h_2(t) e^{j2\pi f_c t} \right]$$

in general $h_2(t)$ is complex

Response of a band pass system to a Band Pass Signal.
 signal is in passband ; channel is in passband \Rightarrow sp passband.

$$r(t) = \operatorname{Re} \left[r_2(t) e^{j2\pi f_c t} \right]$$

$$r_2(t) = \int_{-\infty}^{\infty} s(\tau) h(t-\tau) d\tau$$

So, output $r(t)$ is a convolution of $s(t)$ and $h(t)$. And if we take the Fourier relationship it turns out to be this.

(Refer Slide Time: 00:54)

Handwritten derivation on a whiteboard:

$$R(f) = S(f)H(f)$$

$$= \frac{1}{2} [S_{\lambda}(f-h) + S_{\lambda}^*(-f-h)] [H_{\lambda}(f-h) + H_{\lambda}^*(f-h)]$$

Annotations for the first equation:

- $S_{\lambda}(f-h) = 0$ for $f < 0$
- $S_{\lambda}(f) = S_{\lambda}(f+h)$
- $S_{\lambda}(f-h) = S_{\lambda}(f)$
- $S_{\lambda}^*(-f-h) = 0$ for $f > 0$
- $S_{\lambda}(f) = S_{\lambda}(f+h)$
- $S_{\lambda}(-f) = S_{\lambda}(-f+h)$
- $S_{\lambda}(-f-h) = S_{\lambda}(-f)$

$$R(f) = \frac{1}{2} [S_{\lambda}(f-h)H_{\lambda}(f-h) + S_{\lambda}^*(-f-h)H_{\lambda}^*(-f-h)]$$

Now, we have already seen that $S(f)$ has an expression which is $S(f)$ for $f < 0$ plus $S(f)$ conjugate minus $f > 0$. And $H(f)$ we have already defined here that you can see we have already defined in the previous lecture. So, we followed by the same thing. So, instead of the half you simply have $H(f)$ for $f < 0$ plus $H(f)$ for $f > 0$.

Now if we look into these expressions we could say that $S(f)$ for $f < 0$ is very close to 0 for $f < 0$. And one could argue in a way that in some form, one could say that $S(f)$ for $f < 0$ is $S(f)$ plus $f > 0$ if you remember this. So, then you need to do this translation. So, one could have $S(f)$ for $f < 0$ should be equal to $S(f)$ plus $f > 0$, I would simply replace f by $-f$ for $f < 0$. So, I am going to get this so, this is equal to 0 for $f < 0$ because we have taken only positive set of frequencies over here.

So that means, what we are saying that this value is very small or negligible a 0 for $f < 0$. Similarly if you take this one $S(f)$ for $f > 0$ minus $f > 0$ this value is also 0 for $f > 0$ that is very, very small you could say. To argue on this front you could also set up in a similar way that $S(f)$ for $f < 0$ is equal to $S(f)$ plus $f > 0$ and then $S(f)$ for $f > 0$ is equal to $S(f)$ minus $f > 0$, plus $f > 0$ and then you could say that $S(f)$ for $f < 0$ minus $f > 0$ is equal to $S(f)$ plus $f > 0$. And if I would put $f > 0$ so, you want to get $S(f)$ plus $f > 0$; that means, negative values which is 0.

(Refer Slide Time: 03:46)

Representation of linear Band Pass System

Band pass signal passes through a band pass filter (channel).

$h(t)$ impulse response, which is real

$H^*(-f) \equiv H(f)$

$$H_2(f - f_c) = \begin{cases} H(f) & f > 0 \\ 0 & f < 0 \end{cases}$$

$$H_2(+f - f_c) = H(f) \quad f > 0$$

$$H_2^*(f - f_c) = H^*(f) \quad f > 0$$

$$H_2^*(-f - f_c) = H^*(-f) \quad f < 0$$

$$= 0 \quad f > 0$$

$$H(f) = H_2(f - f_c) + H_2^*(+f - f_c)$$

$S_2(f) = S_+(f + f_c)$
 $S_2(f - f_c) = S_+(f)$
 $= 0 \quad f < 0$

So that means, this thing is nearly 0 for f less than 0 and this thing is nearly 0 for f negatives similarly if we go by the definition of h of f , what you have over here. What we see is that this is $H f$ for f greater than 0, 0 for less than 0 and this quantity is 0 for f greater than 0. So, we could we could say at this is almost equal to 0 for f greater, than 0 this is almost equal to 0 for f less than 0 in a same manner.

Now if we see these things. So, for f less than 0 what will find is only these 2 terms exist right. Whereas, for f greater than 0 this term goes to 0 this term goes to 0 for f greater than 0. So, for f greater than 0 only these 2 terms exist. So, we could have this is half that stays with us as $S | f$ minus $f c$, this gets multiplied with this $h | f$ minus $f c$ right. And for the other half; that means, for f less than 0 we have $S |$ conjugate minus f minus $f c$ sorry this will be $h |$ conjugate, minus f minus $f c$. Now if we look at these relationships.

(Refer Slide Time: 05:07)

$$R(f) = \frac{1}{2} [R_x(f-h) + R_x^*(-f-h)]$$

when $R_x(f) = S_x(f) H_x(f)$

$$r_x(t) = \int_{-\infty}^{\infty} s_x(\tau) h_x(t-\tau) d\tau$$

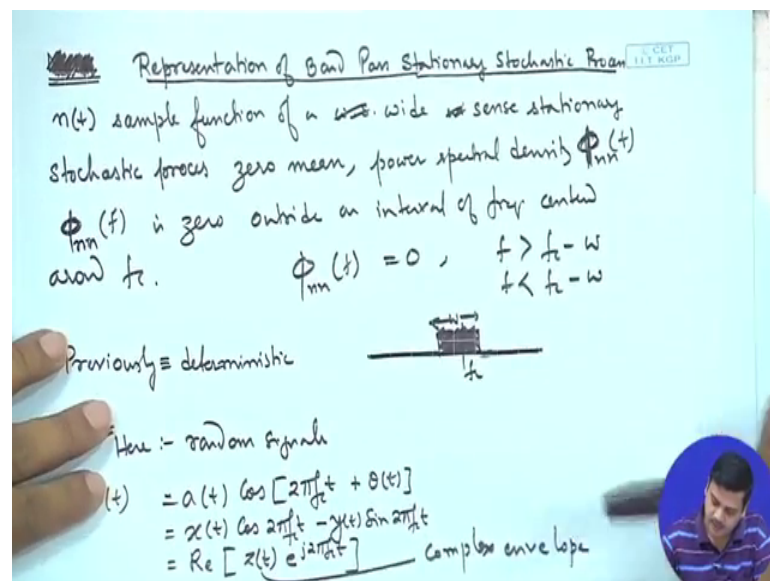

That are available with us, what we could say is that we could write this potentially as half. $R_l f$ minus $f c$ plus R_l conjugate minus f minus $f c$ right.

So, in other words we could say that where these relationships make sense if only we would define R_l of f is equal to S_l of f multiplied by H_l of f . And therefore, we could see that we could relate this R of f over here, and this is R of f over here to it is low pass equivalent form in the same way and since r of R_l of f is related to S_l of f and H_l of f . In this way we can say that we low pass equivalent signal and the channel could help us in getting the pass band spectrum of this particular signal and since this is a multiplication in the in the Fourier domain in the in the frequency domain. So, what we have is R_l of t what we are defined before you could write this as convolution of S_l of t and h_l of t .

So, this is what you could write as the relationship between the 2 signals; that means, the low pass equivalent in terms of the low pass equivalent signal and the system. So that means, this way we can say that if we take this relationship and if we would take this relationship that we have here with us. Together we could make, together we could say that you can find the outcome of the system which when excited by a passband signal. So, the channel is passband, the passband output is $r t$ and you could relate it through the low pass representation of the signal as well as that of the system.

So that means, once again we have been able to show that given a low pass equivalent representation you can well easily translate to the corresponding passband signals representation between the time domain or between the frequency domain. One could also calculate and relate the energies of the low pass equivalent to it is passband equivalent right. So, we continue in this same mode, but now what we would like to do is we have to look at noise. Noise is very important.

(Refer Slide Time: 08:11)

So, we said in the beginning noise is one of the important aspects. So, when you talk about noise of course, what we are going to do immediately is not noise will apply always us to noise. So, you may think of noise as stochastic process or the outcome for stochastic process. And as a stochastic process you can you can describe it in terms of a random variable which takes values as a function of time.

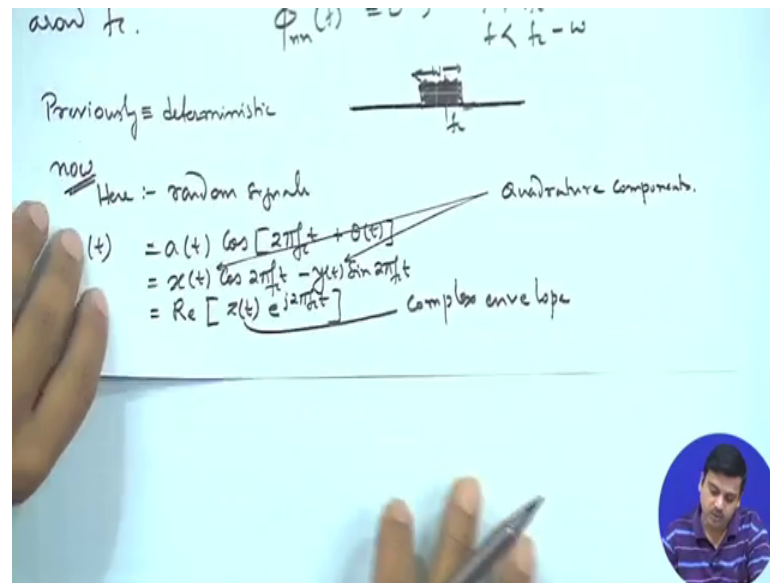

So that means, it is a time evolution of a random process. So, when we said noise we will finally, come to noise and we will see how is it represented and what are it is relationship in the passband with that of the low pass equivalent and how do we take care of this. So, what we will consider is suppose $n(t)$ that $n(t)$ be a sample function of a wide sense stationary. So, let me write this down equal of a wide sense stationary stochastic process with. So, what we are writing rather I would not put noise in this particular, we are going to discuss noise, but what going to what we are going to do is with presentation of band pass stationary, stationary stochastic process.

So, once we do this we will find how noise relates to this description and then whatever we derived in this particular thing would be directly applicable to that of noise. So, let $x(t)$ be the sample function of a wide sense stationary stochastic process. And we also state that this is 0 mean and power spectral density $\phi_{xx}(f)$. So, $\phi_{xx}(f)$ is given where we are saying that $\phi_{xx}(f)$. So, writing $\phi_{xx}(f)$ to represent the power spectral density. What we could do is, there might be a confusion of notation. So, we will put $\phi_{xx}(f)$, as the noise is defined in such a way that this is 0 outside and interval of frequency centered around f_c . So that means, what we are saying is this $\phi_{xx}(f)$ is equal to 0 for f greater than $f_c + w$ and for f less than $f_c - w$. And within this band; that means, if there is a band w so, within this band it has some values right.

What we are not saying that it is defined within this band. It is here elsewhere it is 0 it is centered around this f_c . So, we see that there is lot of similarity with what we have done already before, except what we said. What we need to state is previously, what we did previously we did deterministic signals and now that we are handling here we are talking about random signals. So, you may recall in one of the earlier discussions we said that how could you characterize signals. So, the previous section that we just did is about deterministic signals and here since we are dealing with noise or we are talking about stochastic process, which has the senior and randomness we are basically talking about signals which are randomly in nature.

So, we already have encountered some of the characterization of signals which we have started off with.

(Refer Slide Time: 12:45)

So, in such a case when this is what we have with us we can write, we can write that $n(t)$ could be represented as $a(t) \cos 2\pi f_c t + \theta(t)$. Now this again holds true which you could write in terms of $x(t) \cos 2\pi f_c t - y(t) \sin 2\pi f_c t$, and again which you could write it as real part of $z(t) e^{j2\pi f_c t}$. So, please note here that all that we have said here is, this is a sample function of a signal which is band limited to w centered around f_c . And w is much, much smaller than f_c , it is a narrow band signal and whatever be the signal, if it is narrow band and centered around f_c . You could represent it in a form which is something like this and of course, $z(t)$ is the complex envelope right of, of this.

So, now what we will deal with is, at this point you have said something. At this point we said that it is a wide sense stationary process right. So, if it is wide sense stationary process. So, we write W.S.S. in short. So, since it is wide sense stationary, we would get this $\phi_{xx}(\tau)$ which is the autocorrelation of the quadrature component, x quadrature component x and y are the quadrature components of $n(t)$. So, you could write these 2 is quadrature components. Why we call it quadrature? Because this is on the cosine this is with the sin. So, this is on these 2 sin and cos they are at quadrature ninety degree phase shifted. So, this is you can amplitude of this, is the amplitude of the sin component. So, we call these the quadrature components of noise.

(Refer Slide Time: 15:17)

W.S.S.

$$\Rightarrow \phi_{xx}(\tau) = \phi_{yy}(\tau)$$

$$\phi_{xy}(\tau) = -\phi_{yx}(\tau)$$

Equation Operator

$$\phi_{mn}(\tau) = E[m(t)m(t+\tau)] \text{ Auto correlation of } m(t)$$

$$= E\left[\left(x(t)\cos 2\pi f_c t - y(t)\sin 2\pi f_c t \right) \left(x(t+\tau)\cos 2\pi f_c (t+\tau) - y(t+\tau)\sin 2\pi f_c (t+\tau) \right) \right]$$

$$\phi_{xx}(\tau) = E[x(t)x(t+\tau)]$$

$$= \phi_{xx} C_x C_{t+t+\tau} + \phi_{yy} S_t S_{t+\tau} - \phi_{xy} S_t C_{t+t+\tau} - \phi_{yx} C_t S_{t+\tau}$$

$$E[y(t)x(t+\tau)]$$

So, ϕ_{xx} is the correlation of the, of the b component you can say is equal to ϕ_{yy} of τ and you will also get ϕ_{xy} of τ is equal to ϕ_{yx} of τ . What will do very quickly, is we would like to see whether this is true in very quick steps. And then will use these property to find use these relationships to find some important relationships between the passband and low pass spectrum, power spectral density as well as autocorrelation function of this noise. Now we should be careful at this point that if it is deterministic signal, we are dealing with the low pass representation of the signal and the passband representation of the signal. We are talking about the spectrum of the low pass equivalent as well as we are talking about the spectrum of the passband.

Now if it is noise you do not have a representation of the signal, you do not have a form of representation that it will evolve with time. So, in that case we are rather interested in autocorrelation functions we are interested in the power spectral density to represent or which characterize these processes. So, with the help of these will see how things are. So, will start off with expectation of $n(t)$ with $n(t+\tau)$; that means, we are taking the autocorrelation. So, this is the autocorrelation of $n(t)$. This is expectation E is the expectation operator. So, expectation operator it means that you are taking the ensemble mean; that means, over the pdf. So, we have E we would use this expression of it is of this kind of a form and we will be using that form to arrive at the autocorrelation and power spectral density.

So, we have $x \cos(x) + t \cos(2\pi f c t)$ plus, minus $y \sin(2\pi f c t)$, this is $n t$. And we also have $x \cos(t + \tau) + \cos(2\pi f c t + \tau)$ minus, $y \sin(t + \tau) + \sin(2\pi f c t + \tau)$. This is what we have with us. And we are going to get an x with x multiplication, x with y multiplication, y with x and y with y . So, when we have the x with x term we are going to have $x \cos(t) \cos(t + \tau)$, and we will be having along with that the \cos of t and \cos of $t + \tau$.

So, when we have this, this expectation operator would work on $x t$. Because $x t$, as we see here is the component of noise in the i phase and y of t is the component along the sorry this is along the i this is along the q right. So, when we apply expectation operator on $n t$ it could apply on this and this because this is deterministic part, there is no randomness in this, this complete deterministic with randomness in x of t .

So, what we have done here in this representation if it makes you confused. It is basically translating this x and y which is the baseband or low pass equivalent parts to the pass band by means of this carrier right. Things will be clearer with more later on. So, when we have this expectation operator this will work on $x t$ and $x t$ and not an $\cos t$. So, that is So, we will have ϕ_{xx} of τ is basically $e^{j(2\pi f c \tau)}$.

So, similarly we are going to write all the relationships. So, what we will get here is ϕ_{xx} of τ , I will writing short $\cos(2\pi f c t)$ and $\cos(2\pi f c t + \tau)$. I will write this in short, and we will get along with that plus ϕ_{yy} , look at this y and this y we are going to get $\sin(2\pi f c t)$ into $\sin(2\pi f c t + \tau)$. And then you want to get $e^{j(2\pi f c \tau)}$ and y you are going to get this cross term. So, when you get this cross term you are going to get a minus and in this case also you are going to get a minus. So, we are going to get 2 terms that is ϕ_{xy} of τ along with $\sin(t) \cos(t + \tau)$, and we will get another term ϕ_{yx} of τ with the $\cos(t) \sin(t + \tau)$. So, this term x you see there is a t so that means, we are having this term and we are having this term.

So that means, these 2, these 2 terms right. So, these 2 terms make this particular product. So, what we have is expectation of y of t and x of $t + \tau$ is written over here. Similarly this term is a result of this and this. So, that is how this relationship come. At this point we would have to use some of the trigonometric expansion.

(Refer Slide Time: 21:49)

$$\begin{aligned}
 C_A C_B &= \frac{1}{2} [C_{A-B} + C_{A+B}] \\
 S_A S_B &= \frac{1}{2} [C_{A-B} - C_{A+B}] \\
 S_A C_B &= \frac{1}{2} [S_{A-B} + S_{A+B}]
 \end{aligned}$$

$$\begin{aligned}
 \phi_{xx}(z) &= \phi_{yy}(z) \\
 \phi_{yx}(z) &= -\phi_{xy}(z)
 \end{aligned}$$

$$\begin{aligned}
 \phi_{nn}(z) &= \frac{1}{2} [\phi_{xx}(z) + \phi_{yy}(z)] C_{2\pi f_c z} \\
 &+ \frac{1}{2} [\phi_{xx}(z) - \phi_{yy}(z)] C_{2\pi f_c 2t+z} \leftarrow \\
 &- \frac{1}{2} [\phi_{yx}(z) - \phi_{xy}(z)] \sin 2\pi f_c z \\
 &- \frac{1}{2} [\phi_{yx}(z) + \phi_{xy}(z)] \sin 2\pi f_c z \leftarrow \\
 \phi_{nn}(z) &= \phi_{xx}(z) \cos 2\pi f_c z - \phi_{yx}(z) \sin 2\pi f_c z
 \end{aligned}$$

n(t) = WSS

Cos of A times cos of B is half cos A minus B plus cos A plus B. So, I am writing this for cos not another C right. The suffix and sin of A sin of B is half cos A minus B minus cos A plus B, as well as sin A cos B is equal to half sin A minus B plus sin of A plus B.

So, equipped with these things and when we see this particular expression here above. This particular expression is sufficient for us what we can say is cos of A plus B that is here we can expand in terms of cos of A minus B cos of A plus B. So, then you are going to have cos of A minus B. So, where you are going to be left with the cos of tau; that means, $2\pi f_c \tau$ and the second term, will be cos of $2\pi f_c 2t + \tau$ because you are going to have this thing right. So, will be writing these terms accordingly and what you can get is ϕ_{nn} of tau that is what we have here, that is what we have here ϕ_{nn} of tau is ϕ_{xx} tau is equal to this you can say this right. So, that particular term what we have before would work out to half ϕ_{xx} of tau plus ϕ_{yy} tau into $\cos 2\pi f_c \tau$. And you are going to get half ϕ_{xx} of tau minus ϕ_{yy} of tau into $\cos 2\pi f_c 2t + \tau$. Similarly you are going to get other terms ϕ_{yx} of tau minus ϕ_{xy} of tau times $\sin 2\pi f_c \tau$ and minus of half ϕ_{yx} of tau plus ϕ_{xy} of tau into sin, I would in short, I would like to $t + \tau$.

We have said that $n(t)$ is stationary. So, if we say that $n(t)$ is a stationary then what we mean is that we said wide sense stationary that autocorrelation function of $n(t)$ is dependent only on the lag time and not dependent on time; that means, if you look at this

expression here. This expression should not have any dependence on t , if $n(t)$ is wide sense stationary the right hand side should not have any dependence on t . For it not to have dependence on t this term and this term which have dependence on t should go to 0 so; that means, we can conclude from this if this has to go to 0 this coefficient should be 0 so; that means, ϕ_{xx} of τ should be equal to ϕ_{yy} of τ . And if this coefficient should go to 0 then what we have is ϕ_{yx} of τ is equal to minus ϕ_{xy} of τ . And this is what we started off with when we talked about the wide sense stationary.

So, if you look at this ϕ_{xx} τ equal to ϕ_{yy} τ ϕ_{yx} of τ is equal to minus ϕ_{xy} of τ so, minus sign goes on either side. So, this is a very important result that we have for wide sense stationary narrow band pass process. So, along with this So, if we are going to fit it back what you are going to get is ϕ_{nn} τ now since these 2 are equal. So, ϕ_{yy} equals to ϕ_{xx} this is equal to $2 \times$. So, we are going to get ϕ_{xx} of τ this term is going to 0 and this term is going to 0. So, we are left with this. So, you have ϕ_{yx} is equal to minus ϕ_{xy} . So, you are going to have ϕ_{xy} . So, ϕ_{xy} minus ϕ_{yx} is equal to ϕ_{xy} . So, we can say minus ϕ_{xy} sorry we have a ϕ_{xx} times $\cos 2\pi f_c \tau$ minus, because of this you are going to get ϕ_{yx} of τ $\sin 2\pi f_c \tau$.

(Refer Slide Time: 27:14)

The image shows a hand holding a pen writing on a whiteboard. The equations are as follows:

$$z(t) = x(t) + jy(t)$$

$$\phi_{zz}(t) = \frac{1}{2} [z^*(t) z(t+\tau)]$$

$$= \frac{1}{2} [\phi_{xx}(\tau) + \phi_{yy}(\tau) - j\phi_{xy}(\tau) + j\phi_{yx}(\tau)]$$

$$\phi_{zz}(\tau) = \phi_{xx}(\tau) + j\phi_{yx}(\tau)$$

In the bottom right corner of the whiteboard, there is a small circular inset video of a man speaking.

Then we proceed further and we could say, that if we have z of t remember our z of t what we had z of t here. We had z of t there that it is the complex envelope of $n(t)$.

(Refer Slide Time: 27:26)

$$-\frac{1}{2} [\phi_{yx}(z) - \phi_{xy}(z)] \sin 2\pi f_c z$$

$$-\frac{1}{2} [\phi_{yx}(z) + \phi_{xy}(z)] \sin 2\pi f_c z$$

$n(t) \rightarrow \text{WSS}$

$$\phi_{nn}(z) = \phi_{xx}(z) \cos 2\pi f_c z - \phi_{yx}(z) \sin 2\pi f_c z$$

$$\phi_{zz}(z) = \phi_{xx}(z) + j \phi_{yx}(z)$$

$$\phi_{nn}(z) = \text{Re} [\phi_{zz}(z) e^{j 2\pi f_c z}]$$

So, definitely z t you could write it as, x t plus j y of t and hence, ϕ_{zz} of t is equal to half z conjugate of t times z of t plus τ . So, this is the way of defining, and what you would get you could easily go through a few steps you can get this as ϕ_{xx} of τ plus ϕ_{yy} of τ minus ϕ_{xy} of τ plus j ϕ_{yx} of τ . So, that would mean ϕ_{zz} τ would be equal to ϕ_{xx} of τ plus j ϕ_{yx} of τ .

So, given this relationship one put establish that, let us look at the last relationship that we derived. So, if you look at this relationship that we have derived here, right. Then you could say that ϕ_{nn} τ is equal to real part of ϕ_{zz} τ $e^{j 2\pi f_c \tau}$ right. So, in other words we are saying so, basically this is what we have yeah. So, if you have ϕ_{zz} τ is equal to ϕ_{xx} τ plus this. So, if you do this product you are going to get ϕ_{xx} τ $\cos 2\pi f_c \tau$ minus ϕ_{yx} τ $\sin 2\pi f_c \tau$.

So, this is the form which is very similar to the relationship that you had when we discussed the baseband equivalent and the low pass equivalent and the passband of a signal. So, what we see in case of stochastic process we basically have the correlation functions related in a similar manner that we have for the signal. And we have a similar thing for the autocorrelation function and it is in phase and quadrature phase components. So, we have discussed a few important properties of baseband signals and passband equivalents. We have also seen the relationship of the autocorrelation function

for the narrowband stochastic process. What we need to see now in the next lecture is the spectral relationship of the narrowband stochastic process and its relationship to noise.

Thank you.
