Lecture - 25
Lattice Formulations Of Linear Prediction (Contd.)

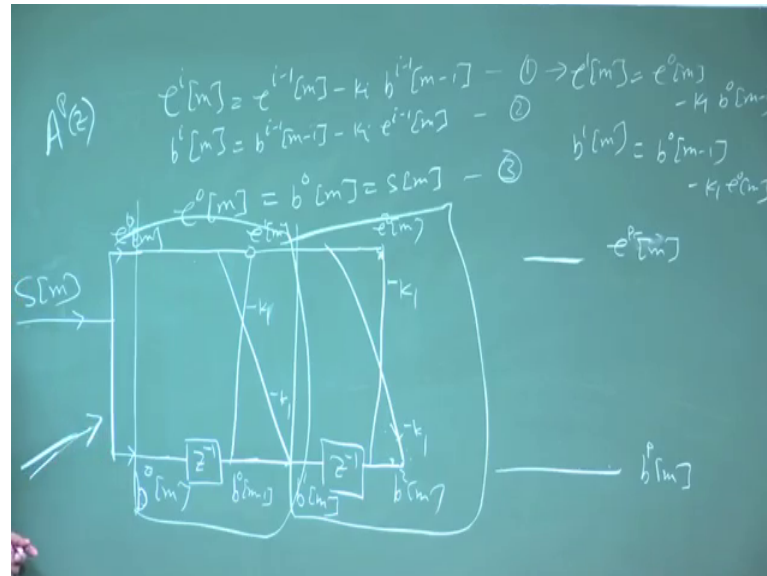

(Refer Slide Time: 00:18)

So we have derived these 2 equation. So, forward error ith order forward error is nothing, but a previous 1 minus previous backward error multiply by the k_i , so this 2 equation; we have derived. Now, if I am not predict anything; what is $e_0[m]$; what is $e_0[m]$? $e_0[m]$ means that what is error? Error is that sample value minus estimated value. So, if order is 0; that means, I am not estimating anything. So, error is nothing, but a $s[m]$. So, similarly backward error is also is nothing, but a $s[m]$. So, I can say $e_0[m]$ is equal to $b_0[m]$ is equal to $s[m]$.

Now, try to draw the signal flow diagram or I try to draw the equation lattice filter structures using these 3 equations. So, let this is the equation number 3.

(Refer Slide Time: 01:23)

So, what I say if I know $S[m]$ I know $b^0[m]$. So, which give me the $e^0[m]$ and $b^0[m]$; now let us I want to find out the $e^1[m]$; I want to find out $e^1[m]$. So, what is $e^1[m]$? From this equation if I say $e^1[m]$ is nothing, but a $e^0[m]$ minus k_1 into $b^0[m]$ minus 1. So, what is b^0 ? This is $b^0[m]$. So, if it is $b^0[m]$; I want to produce $b^0[m]$ minus 1. So, I can say Z to the power minus 1.

So, $S[m]$ is feeded here; speech signal is feeded here. So, $e^0[m]$; $b^0[m]$ is equal to $S[m]$; Z to the power minus 1 delay if I applied, I get $b^0[m]$ minus 1. Now, $e^0[m]$; $e^0[m]$ is nothing, but a $e^0[m]$ minus k_1 into k_1 into $b^0[m]$ minus 1. Similarly, suppose I want to predict $b^1[m]$. So, $b^1[m]$ backward prediction error; $b^1[m]$ again I put the; i equal to 1 in here. So, I can say $b^0[m]$ minus 1 minus k_1 ; $e^0[m]$, so I can say this one is nothing, but a this is $e^0[m]$, this will be minus k_1 .

So, if I say that I want to predict $e^2[m]$ and I want to predict $b^2[m]$. So, again I have to delay; one delay Z to the power minus 1 and I can say this signal should be added here with minus k_1 and this signal should be added here to get the $b^1[m]$ minus k_1 . So, if you see the same structure is repeated here. So, this is called lattice structure; single lattice, second lattice, third lattice and that way I can get the value of $e^p[m]$; if the p th order prediction.

So, I get $e^p[m]$ and from here I get $b^p[m]$; so, that is called lattice structure. So, what is $e^p[m]$? $e^p[m]$ is nothing, but a error. So, if I say I want to implement $A^p(z)$; this is the implementation of $A^p(z)$; why? If you remember in my first class, what I am saying that

if the whole speech production system is linearly model; LTI system or linearly model then I can say; if I apply if this is my H Z is my vocal track transfer function; H Z in here.

(Refer Slide Time: 04:51)

So, what I said; if we apply impulse A U, G Z; glottal impulse with amplitude, then I get speech signal; which is S Z or I can say in time domain I can write A U g m; this is and I get S m.

What is H Z? H Z is nothing, but a gain either A or write G; gain; A or G; I can write the gain as G also. So, I write the gain as A, G. So, G by 1 minus K equal to 1 to P alpha K Z to the power minus k. So, this is nothing, but a prediction error; which is H Z. So, I can say H is equal to G by A Z; G is a constant.

So, I can replace that A Z by 1 by A Z or I can say; if I apply A Z, if I implement A Z and apply S Z; I can get error E Z; which is nothing, but a I can get E Z or forward prediction error or backward prediction error; at the pth state both will be same E Z or I can say, if I apply S m; time domain signal and if I implement this A Z, I will get E Z; epm or which is nothing, but a G into U g m.

So, from output speech; speech is nothing, but a excitation into the transfer function. So, this is A Z. So, if I this if I subtract this one only remaining is the glottal excitation. So,

that is gain into glottal excitation; so, error function is nothing, but a gain into glottal excitation.

So, suppose for a given speech signal; find out the prediction error or prediction error signal which is nothing, but a gain into glottal excitation signal. So, I can apply the speech signal and implement A Z; I can implement easily A Z; if I know K 1; value of K 1; K 2; in second stage; it will be K 2. So, third stage it will be K p; so, if I know the value of K 1, K 2, K P and if I implement this diagram; this thing in digital computer and then if I apply speech signal, I get the excitation signal.

So, this is called prediction lattice filter for A Z or error filter implementation lattice filter for A Z or error filter implementation. Now, suppose in speech synthesis; so, let us I told you a one thing; suppose I have a speech signal which has let us 8 kilohertz sampled signal.

(Refer Slide Time: 08:25)

And let us I take a window of 20 millisecond and it is encoded yet let us 8 bit 8 kilohertz 8 bit. So, in 20 millisecond; how many samples will be there? 160 samples will be there. Now, each sample is 1 byte; so, I can say this 20 millisecond window can be stored or can be required 160 byte memory to store.

Now, suppose the problem is that I want to transmit this 20 millisecond speech from this point to this point. So, my bit rate is 160 byte I have to transmit it; I have to transmit it

160 byte from this point to this point. Can I reduce it using this LPC method? So, instead of transmitting 20 millisecond, so since it is 8 kilohertz; what should be the order of the prediction? So, for F_s is equal to 8 kilohertz; so I can say F_s by 1000 plus 20 for radiation and 2 for glottis. So, I can say it is nothing, but a 8 plus 2 plus 2; twelfth order prediction is required; 12 to 14 order prediction is required.

What is the meaning is that; that means, that I required α_1 to α_{12} . So, if it is α_1 to α_{12} and each one of the α is encoded with let us encoded with 4 byte let us take 4 byte. So, 4 into 12; 48 byte; I require to encoded the α value; now it is said that if I know the α value or K value K_i value let us say K_i value. So, if I know the K_i value; then at the receiving side I can say that I can implement the filter which is 1 by AZ and I can implement 1 by AZ .

And if I apply the gain and error signal; what is error signal nothing, but a excitation. So, excitation if it is voice; then it excitation is nothing, but a impulse if it is unvoiced excitation nothing, but a noise. So, what information extra things I require? Whether of this segment is voiced or unvoiced that require 1 byte; 1 bit, if it is one then it is voice; if it is 0 then it is unvoiced.

Next if it is voiced then I have to generate the impulse who supply the impulse do you know? That is also transmitted. So, I can say again the value of f_0 will be also transmitted. So, if f_0 value is transmitted using 1 byte; let us f_0 value and this voice unvoiced information is transmitted using 1 byte. So, 48 byte plus 1 byte let us 49 byte is required.

So, if I transmit instead of 160 byte; I can transmit forty nine byte and require the signal same segment at the receiver end this is called LPC encoding. So, in LPC encoding; I only transmit this α value; why that is a voiced and unvoiced or f_0 value and then receiver side I connect. So, I can say if I want to draw the decoder. So, I can say if it is voiced let us this is a impulse generator.

(Refer Slide Time: 12:34)

Then there is a gain let us gain also transmitted G 1 byte. So, gain is transmitted using 1 byte; so, it is 50 byte. So, this is gain this is multiply with gain; this is gain, this is noise source. There is a switch; if it is voiced, the switch will be connected to here; if it is unvoiced it will be connected to here. And then I implement 1 by A Z which is supply from K i value; then I get the speech signal back.

So, how do you implement A Z? I know how to implement A Z? Now, I know that if it is A Z and H Z is nothing, but a G by A Z. So, I want to implement 1 by A Z; I have to implement 1 by A Z how do I implement 1 by A Z? A Z implementation is already explained. So, I have to again I have to implement 1 by A Z; which is nothing, but a H Z. This is required; this is called a lattice formation of vocal track transfer function, which if I implement that using K i value; from this information, I can generate the speech signal.

So, how do you implement 1 by A Z filter? Let us try to 1 implement 1 by A Z; A Z I can implement from that equation. So, 1 by A Z; so, what I want? I want to supply error signal; epm I know inverse; I want to inverse it.

(Refer Slide Time: 14:21)

So, that why I have applied S m and I get epm; now I say I want to apply epm and reverse the signal and get S m back that is 1 by A Z. So, at the output; what I said? I said epm is the error signal. So, I know epm; let us say epm I know is the error signal I know.

So, if you remember the equation eim is nothing, but a ei minus 1 m minus K i into bi minus 1; m minus 1. So, if I know epm; what I have to estimate? I have to estimate ep minus 1 m. So, if I say e i minus 1 m; is equal to eim plus K i into b i minus 1; m minus 1. So, I can say ep minus. So, instead of i; I put P; e P minus 1 m is equal to epm which I know; plus I have to know this; I have to know b P minus 1 m; m minus 1; b P minus 1 m minus 1 or not.

So, if I say this point is my b P m; so, I have to apply a Z to the power this way; coming this way I can apply Z to the power minus 1 to get b P m minus 1 or not. So, if it is that b P minus; P minus; so, if it is b let us this 1 is b P minus 1 m let us this 1 is b P minus 1; this is b P minus 1 m minus 1.

So, I can say aim b P minus 1 m has to be added here; we multiplication factor K i K 1 which is K 1 is K P; i is equal to P. So, I can say e P minus 1 m is equal to epm plus K P into b P minus 1 m minus one. So, if it is b P minus 1 m minus 1; I can get it, now what is b P m; b P m is nothing, but a b P m is nothing, but a what is b P m? b P I can say b i m is nothing, but a b i minus 1; m minus 1 plus minus K i; e i minus 1 m.

Now, I can say b P m is equal to b P minus 1 m minus 1 minus K P e P minus 1 m. So, I can say; if this is my less this is my b P m; this is my b P m. So, if it is my b P m this is

my $b^p[m]$ let us this point is my $b^p[m]$. So, $b^p[m]$ is nothing, but a $b^{p-1}[m]$ minus 1 into k_p ; so this has to be; so, this is here. So, this I can say this as to be again come $e^p[m]$.

So, it is b^e what is $b^p[m]$? $e^{p-1}[m]$ minus 1 into k_{p-1} has to be come again in here 2 and multiply by minus k_p get the $b^p[m]$. So, if I say I just want to draw the drawing very neatly then I can say this is my figure. So, I can let us this one and I can say this is this one; this direction multiplying factor and these direction multiplying factor. Similarly I can calculate $b^{p-1}[m]$; I can calculate $b^{p-2}[m]$ and draw the figure. So, you can draw the figure in home; you see the slides is there. So, you can see the slides also if you want help; ultimately if you see once I go to the 0; what is $e^0[m]$? So, you can say $e^0[m]$; $e^0[m]$ is nothing, but a $e^1[m]$ plus k_1 into $b^1[m]$ minus 1.

Now, $e^0[m]$ is nothing, but a my $S[m]$; $e^0[m]$ is equal to $S[m]$; so, this is the picture.

(Refer Slide Time: 20:48)

$e^0[m]$ is equal to $b^0[m]$ and if I want to calculate $b^1[m]$; $b^0[m]$, I require $b^0[m]$ minus 1 into k_1 minus 1; so, I can do that. So, this is the implementation of $H(z)$; so, details you can see these slides and you draw this. Now, try to implement in a program also; I can implement this in a program also; so, if you see the algorithm; algorithm is given.

(Refer Slide Time: 21:23)

All-Pole Lattice Filter for $H(z)$

1. since $b^{(0)}[-1] = 0, \forall i$, we can first solve for $e^{(i-1)}[0]$ for $i = p, p-1, \dots, 1$, using the relationship: $e^{(i-1)}[0] = e^{(i)}[0]$
2. since $b^{(0)}[0] = e^{(0)}[0]$ we can then solve for $b^{(0)}[0]$ for $i = 1, 2, \dots, p$ using the equation: $b^{(i)}[0] = -k_i e^{(i-1)}[0]$
3. we can now begin to solve for $e^{(i-1)}[1]$ as:

$$e^{(i-1)}[1] = e^{(i)}[1] + k_i b^{(i-1)}[0], i = p, p-1, \dots, 1$$
4. we set $b^{(0)}[1] = e^{(0)}[1]$ and we can then solve for $b^{(0)}[1]$ for $i = 1, 2, \dots, p$ using the equation:

$$b^{(i)}[1] = -k_i e^{(i-1)}[1] + b^{(i-1)}[0], i = 1, 2, \dots, p$$
5. we iterate for $n = 2, 3, \dots, N-1$ and end up with

$$s[n] = e^{(0)}[n] = b^{(0)}[n]$$

You can go through these algorithm and implement this in a program; so, I give you a task what is the task? Let us record in your own voice, record the vowel [FL] you record vowel [FL] how you record?

(Refer Slide Time: 21:40)

Let us for some time you say [FL] then you take the signal of 20 millisecond from the so, there is a [FL] signal is there. So, from the middle you cut 20 millisecond speech signal. So, record e [FL] vowel with 16 kilo hertz sampling frequency 16 bit encoding then cut 20 millisecond of speech signal. So, let us try for one frame only one frame; then what should the order of the LPC analysis 16 kilohertz.

So, 16 K divided by 1000 into plus 2 plus 2; 2 for glottal 2 for radiation. So, I can say 16 plus 2 plus 2 is equal to 20. So, I can get P is equal to 20 then implement A Z in a program and implement 1 by A Z using a program; in MATLAB or C; anywhere you can write the program implement A Z and 1 by A Z and calculate K i value.

So, I for implementation I require K i value; so K i value can be calculated either using autocorrelation function from there you can calculate K i value or directly you can calculate K i value I will show you the slide how to directly K i can be calculated. So, if I know calculate the K i value then implement A Z and 1 by A Z using a MATLAB program try it. If you have any confusion write my in email or you can forum, you write it that I cannot implement it; then implement A Z; once you implement A Z.

(Refer Slide Time: 23:40)

So, I implement A Z in a program; what is the input? Input is S n; which is 20 millisecond signal of A. So, if it is 16 kilohertz; so, there will be 320 sample value; S m is nothing, but a 320 sample value through A Z and find out the error signal. Now apply this error signal and implement 1 by A Z; same K value; K value will be same both function and see whether you get back the S m or not.

See whether you get back exact em, you apply input to the 1 by A Z and see that whether you get the drawback S m or not. For particular one frame; now if I want to synthesize whole [FL] then the frame will be repeated. So, that implement and told me in the forum report me in the forum implement it.

(Refer Slide Time: 24:51)

Direct Computation of k Parameters

$$e^i[m] = e^{i-1}[m] - k_i b^{i-1}[m-1]$$

Minimize forward prediction error as

$$E_{forward}^i = \sum_{m=0}^{L-1+i} [e^i[m]]^2 = \sum_{m=0}^{L-1+i} [e^{i-1}[m] - k_i b^{i-1}[m-1]]^2$$

$$\frac{\partial E_{forward}^i}{\partial k_i} = 0 = -2 \sum_{m=0}^{L-1+i} [e^{i-1}[m] - k_i b^{i-1}[m-1]] b^{i-1}[m-1]$$

$$k_i^{forward} = \frac{\sum_{m=0}^{L-1+i} e^{i-1}[m] b^{i-1}[m-1]}{\sum_{m=0}^{L-1+i} [b^{i-1}[m-1]]^2}$$

So, this is the direct computation of K parameter; what is the K parameter? How do you calculate the K parameters? So, K value actually minimize the error. So, if I say I am not writing in a board; if you see in the slides K forward. So, e forward prediction error min square forward prediction error this one. So, you know that e^i can be written as $e^{i-1} - k_i b^{i-1}$ that whole square. Now, how do you minimize? I differentiate with respect to k_i and equal to 0.

So, check the differentiation and find out the k_i forward value. I can find out the k_i forward value; once I get the k_i forward value. Similarly, I can calculate the k_i value for backward error then I can say the k is equal parcor; partial reflection coefficient or partial correlation coefficient.

(Refer Slide Time: 25:46)

$$\sum_{m=0}^{L-1+i} [e^{i-1}[m]]^2 = \sum_{m=0}^{L-1+i} [b^{i-1}[m-1]]^2$$

$$k_i^{\text{PARCOR}} = \sqrt{k_i^{\text{forward}} k_i^{\text{backward}}} = k_i^{\text{forward}} = k_i^{\text{backward}}$$

$$= \frac{\sum_{m=0}^{L-1+i} e^{i-1}[m] b^{i-1}[m-1]}{\left(\sum_{m=0}^{L-1+i} [e^{i-1}[m]]^2 \sum_{m=0}^{L-1+i} [b^{i-1}[m-1]]^2 \right)^{1/2}}$$

So, if I say that partial correlation coefficient in k_i ; then it is nothing, but root over of K_i . k_i forward equal to K_i backward; then either K_i forward or K_i backward you can take.

(Refer Slide Time: 26:12)

Direct Computation of k Parameters

- minimize **sum** of forward and backward prediction errors over fixed interval (covariance method)

$$E_{\text{burg}}^{(i)} = \sum_{m=0}^{L-1} \left\{ [e^{(i)}(m)]^2 + [b^{(i)}(m)]^2 \right\}$$

$$= \sum_{m=0}^{L-1} [e^{(i-1)}(m) - k_i b^{(i-1)}(m-1)]^2 + \sum_{m=-\infty}^{\infty} [-k_i e^{(i-1)}(m) + b^{(i-1)}(m-1)]^2$$

$$\frac{\partial E_{\text{burg}}^{(i)}}{\partial k_i} = 0 = -2 \sum_{m=0}^{L-1} [e^{(i-1)}(m) - k_i b^{(i-1)}(m-1)] b^{(i-1)}(m-1)$$

$$- 2 \sum_{m=0}^{L-1} [-k_i e^{(i-1)}(m) + b^{(i-1)}(m-1)] e^{(i-1)}(m)$$

$$k_i^{\text{burg}} = \frac{2 \sum_{m=0}^{L-1} [e^{(i-1)}(m) \cdot b^{(i-1)}(m-1)]}{\sum_{m=0}^{L-1} [e^{(i-1)}(m)]^2 + \sum_{m=0}^{L-1} [b^{(i-1)}(m-1)]^2}$$

- $-1 \leq k_i^{\text{burg}} \leq 1$ **always**

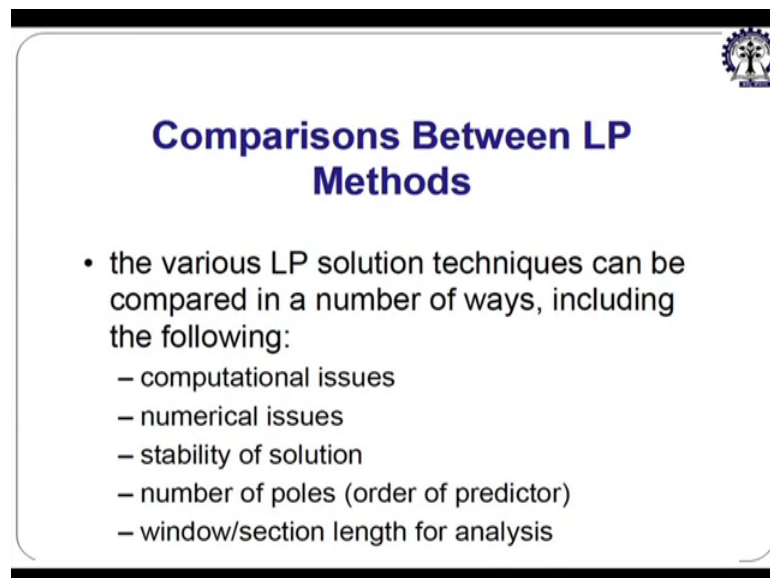

17

Or you can use covariance methods which is equivalent to call; I can say barge method. So, total error is forward error plus backward error; so, min square error forward error square plus backward error square and then take the differentiation with respect to K_i and make it 0 and find out the value of K_i burg. So, if you know K_i you can implement A Z or if you know e_i one m and e_i . So, based on the previous error; I can find out

present k_i ; so, using this equation you can implement A Z or 1 by A Z and record a vowel [FL] take a 20 millisecond window; pass through A Z find out em then pass the em with 1 by A Z implementation and get back that S m again.

So error signal consist of excitation and gain; if it is noise signal if it is picketing sound then it is nothing, but a gain and noise.

(Refer Slide Time: 27:37)

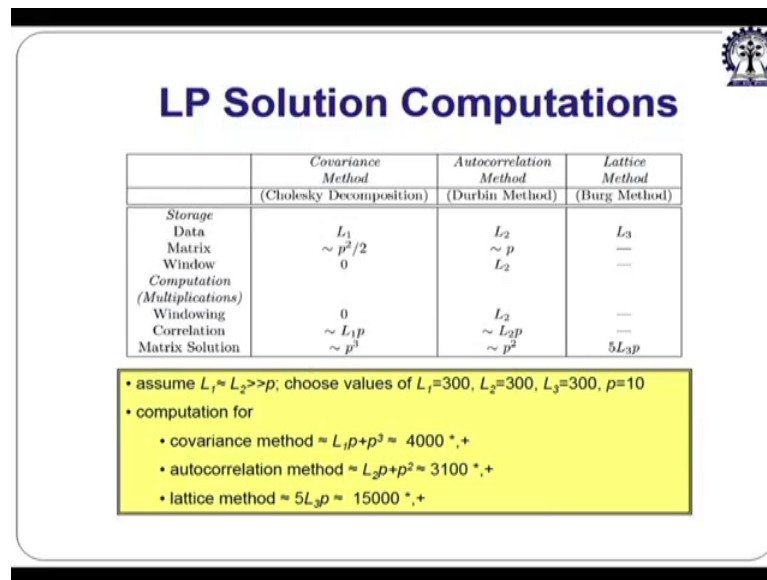

The slide features a title 'Comparisons Between LP Methods' in bold blue text. Below the title is a bulleted list of comparison criteria. The slide is framed by a black border at the top and bottom, and a thin grey border on the sides. A small logo is visible in the top right corner of the slide area.

Comparisons Between LP Methods

- the various LP solution techniques can be compared in a number of ways, including the following:
 - computational issues
 - numerical issues
 - stability of solution
 - number of poles (order of predictor)
 - window/section length for analysis

So, this is the summary now comparison; you may compare the different methods; what have the different methods for a LP extraction? If you see that lattice method only use, combine the 2 stage covariance that correlation or autocorrelation or correlation matrix and linear solution; they are combined both together and use single instance.

(Refer Slide Time: 28:04)

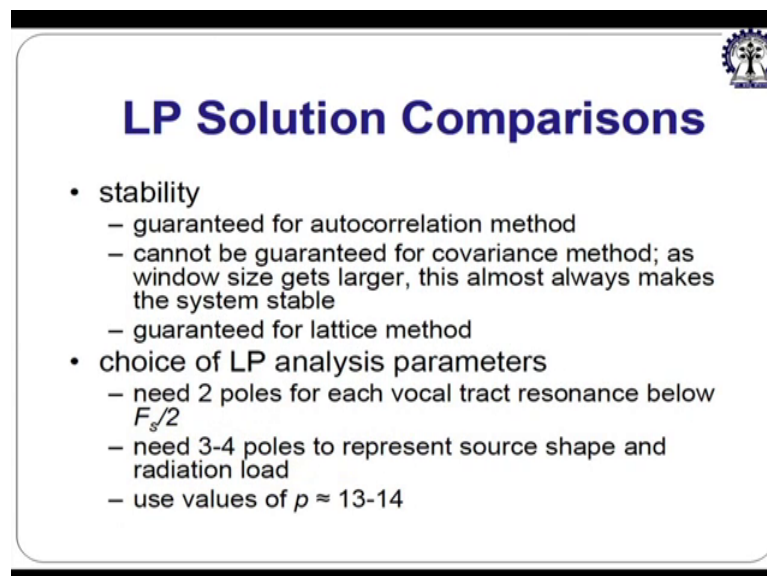

LP Solution Computations

	<i>Covariance Method</i> (Cholesky Decomposition)	<i>Autocorrelation Method</i> (Durbin Method)	<i>Lattice Method</i> (Burg Method)
<i>Storage</i>			
Data	L_1	L_2	L_3
Matrix	$\sim p^2/2$	$\sim p$	—
Window	0	L_2	—
<i>Computation (Multiplications)</i>			
Windowing	0	L_2	—
Correlation	$\sim L_1 p$	$\sim L_2 p$	—
Matrix Solution	$\sim p^3$	$\sim p^2$	$5L_3 p$

- assume $L_1 \approx L_2 \gg p$; choose values of $L_1=300$, $L_2=300$, $L_3=300$, $p=10$
- computation for
 - covariance method $\approx L_1 p + p^3 \approx 4000$ *, +
 - autocorrelation method $\approx L_2 p + p^2 \approx 3100$ *, +
 - lattice method $\approx 5L_3 p \approx 15000$ *, +

So, those are the computational issue is there, you can read it from that slides.

(Refer Slide Time: 28:08)

LP Solution Comparisons

- stability
 - guaranteed for autocorrelation method
 - cannot be guaranteed for covariance method; as window size gets larger, this almost always makes the system stable
 - guaranteed for lattice method
- choice of LP analysis parameters
 - need 2 poles for each vocal tract resonance below $F_s/2$
 - need 3-4 poles to represent source shape and radiation load
 - use values of $p \approx 13-14$

Stability issue is there; generate for autocorrelation guaranteed for autocorrelation guaranteed for lattice method. But covariance method it is not guaranteed because if it is a large matrix then you know the upper triangular matrix, lower triangular matrix. So, they are have some problem; so, you can say the covariance method is not guaranteed, but autocorrelation method and lattice method stability is guaranteed. Choice of LP analysis

already I have discussed F S by 1000 or F S by F S by 2, F S by 1000 plus 2 for glottal excitation and 2 for the radiation.

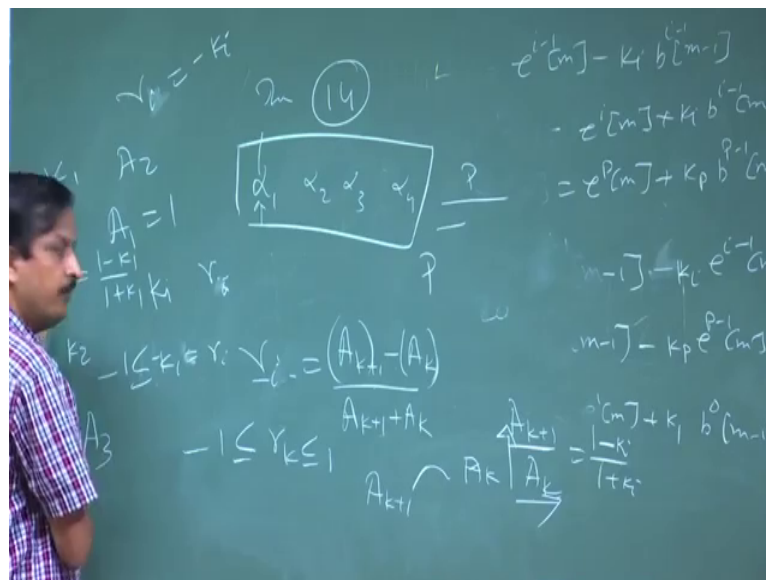

(Refer Slide Time: 28:52)

Estimating Formant Frequencies

- compute $A(z)$ and factor it.
- find roots that are close to the unit circle.
- compute equivalent analog frequencies from the angles of the roots.
- plot formant frequencies as a function of time.

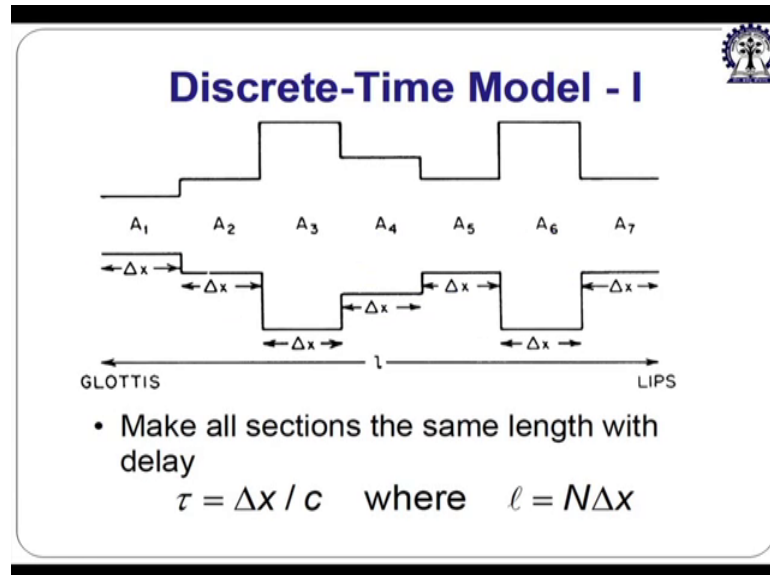

(Refer Slide Time: 28:59)

Estimation of for so, if I know $A(z)$; I have already discussed that if I know α_1 , α_2 , α_3 and all LPC coefficient α_4 ; those represent the transfer function at that position and each pole; if it is those are implemented the pole position equivalent to the pole. So, each pole represent the formant frequency actually α_1 , α_2 , α_3 . should represent the formant frequency is the frequency plane.

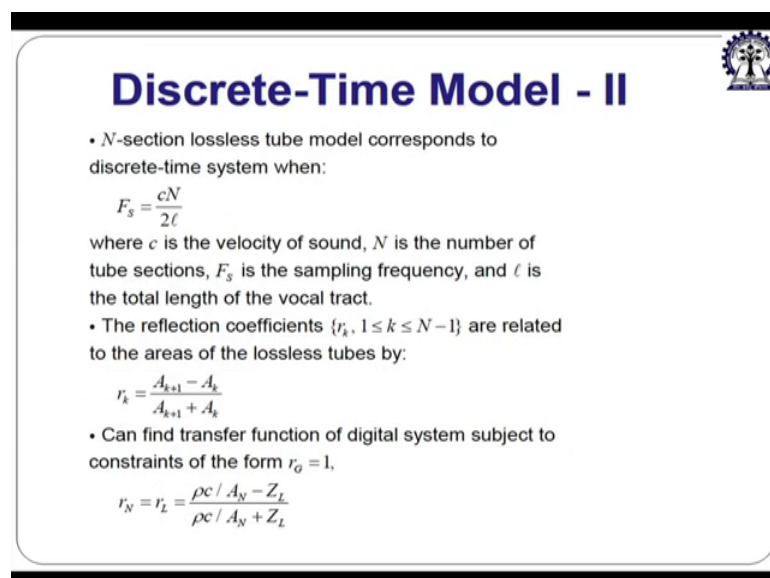

Now, if I take fourteenth order; then the alpha value which is not close to unit circle not give you the formant frequency. So, the alpha value which root value close to the unit circle; give you the formant value.

(Refer Slide Time: 29:47)

Then I have already said in my tube class this LP analysis is related to the loss less tube model. If you remember that this is the lossless tube model, if I consider all tube has same dimension; then I know L equal to N into letter X .

(Refer Slide Time: 29:58)

So, you know that r_k ; value of r_k is nothing, but $A_k + 1$ minus reflection coefficient A_k ; plus 1 plus A_k . So, if I consider r_g is equal to 1; then r_n equal to r_n ; r_g is equal to 1; then r_n is equal to r_l and r_n equal to r_l ; r_l equal to row c_{pi} a an divided by Z_L . So, let us Z_L is equal to 1 also 1; forget about that. So, this is the reflection coefficient.

Now, I give you the problem; the problem is here, can I estimate this area function from the speech signal? I want to estimate that suppose I produce [FL] I want to half the area function is changing during the production of [FL]. So, how this area function is changing; let us this tube is model. So, if it is a p th order LPC analysis. So, I can say the tube is divided into P number of section.

So, if you relate that K_i value and r_{rK} value has a relationship or r_i value has a relationship. So, $1 - K_i$ is equal to r_i ; so, you know that the r_K value is $1 - r_K + 1$. So, r_k is nothing, but a $1 - K_i$ or you can say r_i ; let us say this r_i is equal to $1 - K_i$. Now, if I know r_K value or r_i value then I can express $A_k + 1$ in term of A_k or I can say that $A_k + 1$ divided by A_k is equal to $1 - K_i$, it will become $1 - K_i$ divided by $1 + K_i$ if I put the K_i value.

So, if I know the r_i value; if I know the K_i value I know r_i value, once I know r_i value; I can find out the $A_k + 1$ divided by A_k . So, if I know the previous tube cross sectional area; then I can find out the; what should the cross sectional area of the next tube. So, if I say beginning tube let us A_1 is equal to 1; then I can estimate A_2 ; if I know A_1 ; K_1 .

So, if I say A_1 is equal to 1; then I can find out A_2 ; if I know K_1 ; $1 - K_1$ divided by $1 + K_1$; then if I know K_2 and A_2 ; I can estimate A_3 . So, that way I can say if I know first consequence relation 1; then I can say how the cross sectional area is different cross sectional area is created during the production of that vowel; from where I estimated the K_i value.

So, for a given vowel I can draw this is given taken from the professor Rabiner books that if this is my vowel signal; those of the area function. So, area function I can draw if I know the speech signal. So, reversely if I know the area function I can generate the speech signal that is a tube synthesis. Now, if I know the speech I can find out the what kind of constriction; what kind of different cross sectional area is made during the production of that sound.

Thank you.
