**Lecture - 14**  
**Pole and Zero in Z - Transform**

So, today, we talk about Pole Zero, the concept of Pole Zero in Z transform. So, we have already covered what the Z transform is and what the properties of the Z transform we have covered, and we have already said that the Z transform is used to define the systems. So, pole-zero is the concept of the system.

So, in today's lecture, I will talk about that what are the pole-zero concepts in Z transform and what their significance is. How do you locate that pole-zero in the Z plane? All those things we will discuss today we will cover.

(Refer Slide Time: 00:56)

**Pole and zero**

$$X(z) = \frac{B(z)}{A(z)} = \frac{b_0 + b_1 z^{-1} + \dots + b_M z^{-M}}{a_0 + a_1 z^{-1} + \dots + a_N z^{-N}} = \frac{\sum_{k=0}^M b_k z^{-k}}{\sum_{k=0}^N a_k z^{-k}}$$

$$X(z) = \frac{B(z)}{A(z)} = \frac{b_0 z^M z^M + (b_1/b_0) z^{M-1} + \dots + b_M/b_0}{a_0 z^{-N} z^N + (a_1/a_0) z^{N-1} + \dots + a_N/a_0}$$

$$X(z) = \frac{B(z)}{A(z)} = \frac{b_0 z^{-M+N} (z-z_1)(z-z_2)\dots(z-z_M)}{a_0 (z-p_1)(z-p_2)\dots(z-p_N)}$$

$$X(z) = G z^{N-M} \frac{\prod_{k=1}^M (z-z_k)}{\prod_{k=1}^N (z-p_k)}$$

Handwritten notes on the slide include:  $H(z) = \frac{B(z)}{A(z)} = 0$ ,  $H(z) = \infty$ , and a pole-zero plot with zeros  $z_1, z_2, \dots, z_M$  and poles  $p_1, p_2, \dots, p_N$ .

So, let us talk about X (z). X (z) is a rational function that is a ratio of B(z)/A(z).

$$B(z) = \sum_{k=0}^M b_k z^{-k}$$

$b_k$  is the coefficient, and  $z_k$  is the z domain transfer function. So, X (z) is the A(z) domain transfer function.

Now, if you see how many solutions of  $z$  is available in this equation. So, this is the  $M$ th order equation. So, I can get the  $M$  number of solutions of this equation. So, those  $M$  number of solutions is the. So,  $z$  equal to I can get that  $M$ ,  $M$  number of  $z$  value for which this equation becomes 0. So, that is the solution.

So, that solution each of the solutions is called the position of 0. Why is it 0? Why is this solution of this  $z$  called 0 and the solution of this  $z$  called pole? What is the concept of pole and zero?

Let us say I have a transfer function  $H(z)$ , which is a function of, let us say,  $H(z)$ , by which is given  $B(z)/A(z)$ . Now that I know the  $M$  number for the  $M$  number of those  $z$  values, the  $B(z)$  will become 0. Then what will be the value of  $H(z)$ ?  $H(z)$  will become 0. That is why the solution of  $B(z)$  is called 0. So, since in the  $M$ th order equation, there is an  $M$  number of solutions of  $z$  available, which is why I call  $B(z)$  an  $M$  number of 0.

So, the solution of  $B(z)$  is called the 0 position of the transfer function. What is the pole? So, generally, the physical concept of 0 means for those values, the value of the transformation becomes 0. Now, what is the pole? Pole means thus the value of  $A(z)$  for the value of  $z$  for which  $A(z)$  becomes 0; once you said that  $A(z)$  becomes 0 then I can say  $1/H(z)$  what will be the value of  $H(z)$ ,  $H(z)$  will be infinite.

So, that is why, at the pole, the system will resonate. That is why it is infinite, and the amplitude is infinite. So, the solution of  $A(z)$  is called a pole. So, in. So, if I say that  $z$  plane. So, you can say the solution of this  $z$ . So, if this is my  $(z)$  plane, then the solution of  $B(z)$  will be located somewhere, and here those are called 0. The solution of  $A(z)$  is also located somewhere in the  $z$  plane. Those are called poles.

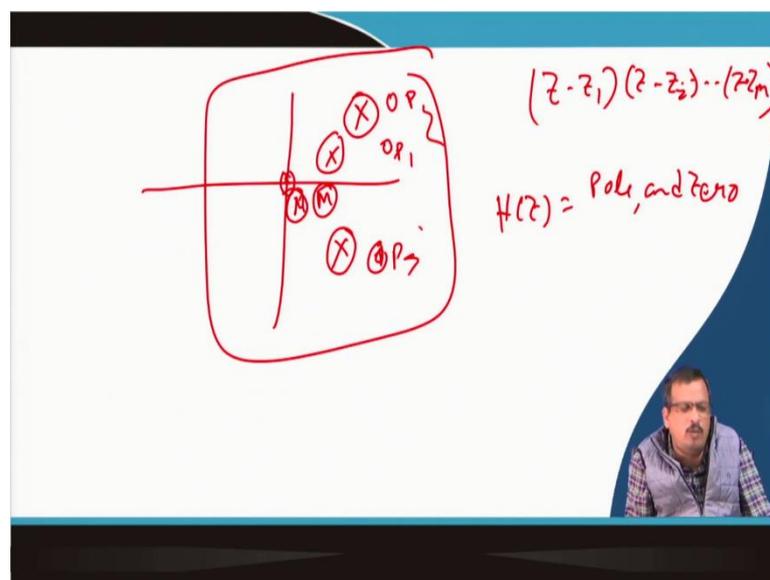

So, this is the concept of pole and zero. Why is it zero? Because for those  $z$  values, the  $H(z)$  becomes zero. Why is it the pole? For those  $z$  value  $H(z)$  becomes infinite. So, that is the pole-zero concept of the  $z$ -domain transfer function.

Now, if you see this is  $z^{-1}$ , I want to make it positive. So,  $z^M$ . So, if I take that  $b_0 z^M$  is outside of this equation, then I can set  $b_0$  as 1. So,  $z^M b_1$  by  $b_0$  into  $z^{M-1}$  plus dot dot  $b_M$  by  $b_0$ .

Similarly, if I want to express in plus in the z domain, I can take that  $a_0 z$  outside, and then I can get  $z$  to the power  $N$  plus this one. Now, if I want to say that the. So, this is the  $M$ th order. This one is the  $M$ th order equation. So, I can say the  $M$  number of solution is possible  $z - z_1, z - z_2, z^M$  for which this value becomes 0. So, those  $z$  values in this  $z_1 z_M$  are called 0 positions, the position of the 0.

So, if I want to plot those values in the z plane, let us say I just take slides, and I will show you that; suppose this is my entire z plane, this is my entire z plane.

(Refer Slide Time: 05:35)

So, this is my entire z plane. So,  $z - z_1$  into  $z - z_2$  dot dot dot dot dot  $z - z_M$  those are those for those  $z$  values that upper portion becomes 0 transfer function becomes 0 that is why those are called 0; let us locate those 0 by a cross.

So, let us say  $(z_1)$  is here. So, this is a 0. Let us say  $(z_2)$  is here. So, this is a 0. Let us say  $(z_3)$  is here, maybe negative; I do not know. So, those are the zero positions of the transfer function in the entire z plane. Similarly, if I said this one  $z - p_1, z - p_2$ . So, for  $p_1$ , these functions become 0.

So, I can show that  $p_1, p_2$ , and  $p_N$  are the poles of the transfer function. So, I can say that, let us say, a pole is represented by a circle. So, this is  $p_1$ , this is  $p_2$ , and this is  $p_3$ . So, all those are poles in the z plane. So, I can analyze the transfer function and determine the

So, I know if I have a system that is  $h[n]$ , if I apply an input of  $x[n]$ , I get  $y[n]$ , which is nothing but a convolution of  $h[n]$  convolved with  $x[n]$  ok. Now, instead of direct convolution in the time domain, what can I do in the  $z$  domain? Suppose I want to find out the transfer function of  $h[n]$  in the  $z$  domain.

So, what I should do is take the  $z$  transform of  $h[n]$ , and I get the  $H(z)$ . I take the  $z$  transform of  $x[n]$ , and I get  $X(z)$  ok. Now, if I get the  $X(z)$  and  $H(z)$ , I can get the  $y(z)$  just by multiplying the  $H(z)$  and  $X(z)$ . Then, suppose I want to get the  $y[n]$ . I take the inverse  $z$  transform of  $y(z)$ , and I will get  $y[n]$ .

Now, suppose I know the output signal and the input signal I want to derive the transfer function. So, if I know the  $y(z)$ , if I know the  $X(z)$ , the transfer function is nothing but a  $y(z)$  by  $X(z)$ . Let us say I have an LTI system, which can be expressed in a constant coefficient differential equation; I have an LTI system, which can be expressed using a constant coefficient differential equation.

So, this is the constant coefficient differential equation

$$y[n] = - \sum_{k=1}^N a_k y[n-k] + \sum_{k=0}^M b_k x[n-k]$$

Now, if I take the  $z$  transform of this, this will not be  $n$ . This will be  $k$ . So, I take the  $z$  transform. So, I know. So, this will be capital  $Y(Z)$ , and this will be capital  $X(Z)$ . So, I can say  $Y(Z)$  if I take the  $Z$  transform, it is

$$Y(z) = - \sum_{k=1}^N a_k Y(z) z^{-k} + \sum_{k=0}^M b_k X(z) z^{-k}$$

Now, if I want to calculate  $Y(z)$  by  $X(z)$ . So, this will be at the top, and this side will go down. So, I can say  $H(z)$  which is nothing, but a  $Y(z)$  by  $X(z)$  is nothing, but a  $k$  equal to 0 to  $M$   $b_k z^{-k}$  divided by  $1 + \sum_{k=1}^N a_k z^{-k}$ .

So, this is my transfer function of  $H(z)$ . So, this is my transfer function. Now, how many zeros are there? How number of zeros are there? How many poles are there?  $N$  number of poles are there? Now, suppose I said that  $M$  has a number of zeros there and  $N$  has a number of poles there.

(Refer Slide Time: 13:52)

The slide contains handwritten notes and diagrams. At the top, it says "If  $a_k=0$  for  $1 \leq k \leq N$  then  $M$  FIR". Below this, it defines an "All-zero system" with  $H(z) = \sum_{k=0}^M b_k z^{-k} = \frac{1}{z^M} \sum_{k=0}^M b_k z^{M-k}$ . A pole-zero plot shows  $M$  zeros at the origin and  $N$  poles at the origin. To the right, a handwritten equation is  $H(z) = \frac{\sum_{k=0}^M a_k z^{-k}}{1 + \sum_{k=1}^N b_k z^{-k}}$ . At the bottom, it says "If  $b_k=0$  for  $1 \leq k \leq M$  then  $N$  IIR". Below this, it defines an "All-pole system" with  $H(z) = \frac{b_0}{1 + \sum_{k=1}^N a_k z^{-k}} = \frac{b_0 z^N}{\sum_{k=0}^N a_k z^{N-k}}$ . A pole-zero plot shows  $N$  poles at the origin and  $M$  zeros at the origin. A small video inset of a man is in the bottom right corner.

So, I can say the

$$H(z) = \frac{\sum_{k=0}^M a_k z^{-k}}{1 + \sum_{k=1}^N b_k z^{-k}}$$

ok. So, there is an M number of zeros and an N number of poles. Now, I said if a k is equal to 0 for k is equal to 1 to n, this part is equal to 0, and the coefficient a k is equal to 0.

So, if this is 0 sorry a k equal to 0 the, this will be sorry this will be a k this will be b k; b k with X and a k with Y. So, this will be a k. So, if it is, I can say that I am sorry. So, a k is equal to 0. So, a k equal to 0 means not this 1 0 this 1 is equal to 0.

So, if this is equal to 0, then I have only the upper portion z k equal to k equal to 1, not 0 k equal to I can say 1 or 0 k equal to 1 to M b k z<sup>-k</sup>. If I want to say make it positive, this 1 is positive instead of -k. So, if I take z to power 1 by z<sup>M</sup>, it becomes z<sup>M-k</sup>.

So, if you see this H(z) only contains M number of 0; M number of 0 and M number of the poles at origin and M number of 0 in the entire z plane, then this is called all zero systems all zero systems.

Similarly, if I say B k is equal to 0, then the upper portion becomes 0, then I can get b0 divided by 1 plus this 1, and so, b0 they again I make it positive. So, b0 to the power z to the power N divided by this 1.

So, this has N number of the poles, N number of 0 at the origin, and N number of the poles in the z plane. So that is called a pole system. So, when I want to implement an LTI system while we discuss the implementation of the LTI system, either it will be an all-pole system or an all-zero system.

When it is a zero system, I can say if M is finite, then it is nothing but a FIR system. If M is finite, it is nothing but a FIR system. When I talk about the all-pole system, it is called an IIR system, or the Infinite Impulse Response system. So, all pole systems are zero systems. So, the z transform is used to determine the transfer function of LTI system H(z), and then I can find out the pole-zero systems I can convert to all pole systems or all zero systems using that Z transform manipulation.

(Refer Slide Time: 17:37)

$$V(z) = \frac{G}{A(z)} \quad A(z) = 1 + \sum_{k=1}^N a_k z^{-k}$$

• If  $V(z)$  is real the roots of  $A(z)$  will be either *real* or occur in *complex conjugate pairs*.

Assume all poles are in conjugated pairs.

$$V(z) = \frac{G}{\prod_{k=1}^{N/2} (1 - a_k z^{-1})(1 - a_k^* z^{-1})}$$

$$a_k = r_k e^{j\theta_k} \quad a_k^* = r_k e^{-j\theta_k}$$

Let us, for example, an application side. Let us say human vocal the human vocal tract can be derived from the mathematical expression of the human vocal track and can be considered as a pole system, which is

$$V(z) = \frac{G}{A(z)} \quad \text{where}$$

$$A(z) = 1 + \sum_{k=1}^N a_k z^{-k}$$

So, there is an N number of poles present in the human vocal tract. I want to give an example. So, let us say V(z) is a real V(z) is a real function and is a real root of agent. So,

$V(z)$  has a real root of the argument. If it is a real root,  $N$  number of poles are there and is the real; then I can say that all poles occur  $N$  number of poles are there. So, if it has to be a real pole, then if it is even complex, that occurs in a complex conjugate.

So, I can say that there is an  $N$  by 2 number of complex conjugate pairs of the pole. What do you mean by complex conjugate pair? Now, suppose I have  $a + jb$  in my 1 pole. Then, if it is a complex conjugate that will be  $a - jb$ , then only multiplication becomes real. So, I can say that  $A(z)$  is real;  $A(z)$  is not an imaginary function. It is a real function.

So, if all roots of the  $A(z)$ 's are real roots, then I can say the  $A(z)$  consists of  $N$  by 2 number of complex conjugate poles. So, if I want to say that, how do I represent  $a + jb$  and  $a - jb$  in a complex plane, this is the real axis, this is the imaginary axis. So, this is  $a + jb$ . is positive when I say  $a$  plus  $a - jb$ , and the amplitude is the same, but only  $\theta$  is negative. So, that is why I can say in the  $A(z)$  plane if it is inside the unit circle. So, this is a unit circle, then it will be a 1, and there will be a 1.

So, those two are complex conjugate pairs. There will be a 2, there will be a 2, there will be a 3, and there will be a 3. Only the  $\theta$  is negative, but the amplitude of the poles is the same because any pole is complex. So,  $a^k$  can be represented  $r^k$  plus  $e^{j\theta k}$   $a + jb$  can be represented in  $r^N \theta$ , which is nothing but  $r e^{j\theta}$ .

So, if it is  $a + jb$ , then  $r e^{j\theta}$ . If it is  $a - jb$ , it is  $r e^{-j\theta}$ . Now, what is the significance? So, how do you relate pole-zero in the physical system? All of you have already known the Laplace transform bode plot. The bode plot is nothing, but the x-axis is the frequency, and the y-axis is the intensity.

So, it is nothing but the frequency response of the system. Similarly, here also from the pole position, the pole which is close to the unit circle basically gives you a resonance frequency; so, each pole corresponds to the resonance frequency in speech application, which is called formant.

So, if I say  $\theta_1$  and  $\theta$  and  $-\theta$  both have the same frequency  $e^{j\theta}$  related to the frequency. So, the same frequency and the formant have a bandwidth if it is not in a unit circle in the origin. So, each pole corresponds to a formant frequency, which is called the resonance frequency of the system.

(Refer Slide Time: 21:54)

The slide contains the following content:

- Pole-zero plot:** A unit circle in the complex plane with two poles at  $r_k e^{j\theta_k}$  and  $r_k e^{-j\theta_k}$  and two zeros at  $a_k$  and  $a_k^*$ .
- Equation 1:** 
$$\text{Let } V_k(z) = \frac{1}{(1 - a_k z^{-1})(1 - a_k^* z^{-1})} = \frac{1}{1 - r_k e^{j\theta_k} z^{-1} - r_k e^{-j\theta_k} z^{-1} + r_k^2 z^{-2}}$$
- Equation 2:** 
$$= \frac{1}{1 - 2r_k \cos \theta_k z^{-1} + r_k^2 z^{-2}}$$
- Equation 3:** 
$$\text{Let } r_k = e^{-b_k} \Rightarrow b_k = -\ln r_k$$
- Equation 4:** 
$$V_k(z) = \frac{1}{1 - 2e^{-b_k} \cos \theta_k z^{-1} + e^{-2b_k} z^{-2}}$$
- Handwritten notes:**
  - $\theta_1 \rightarrow f_1$ ,  $\theta_2 \rightarrow f_2$ ,  $\theta_3 \rightarrow f_3$
  - $\theta \rightarrow \text{resonance}$
  - $V_k(z)$
  - $3 \times 2$
  - A diagram showing three peaks labeled  $F_1$ ,  $F_2$ , and  $F_3$  on a frequency axis.

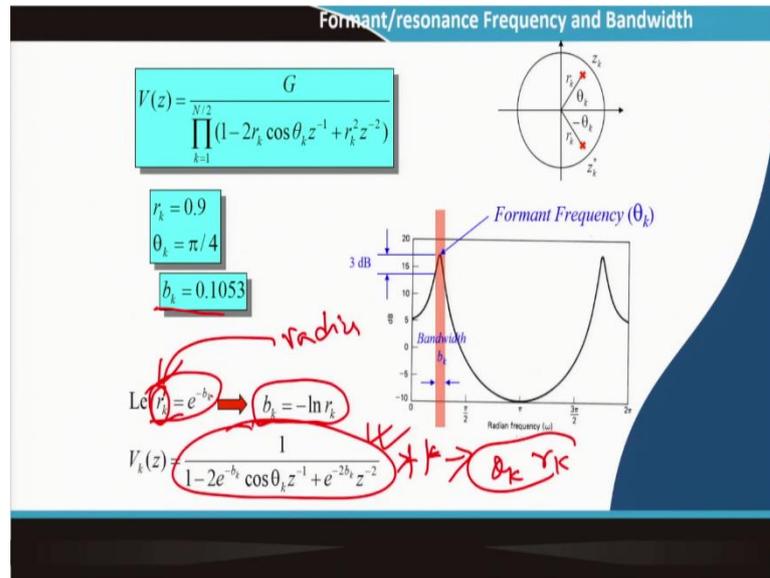

Let us say I have an N number of poles. So, I can plot it. Let us know that this is the  $r_k$ . Let us know if the two poles are there.  $V_k(z)$  is equal to  $1 - a_k z^{-k}$  complex conjugate pole. Those are the complex conjugates. So, if it is a complex conjugate, I can write it down in terms of  $\theta$ .

So,  $\theta$  is related to the resonance frequency, and the  $r_k$  is related to the bandwidth of the resonance frequency. In application,  $\theta$  is related to the resonance frequency, and  $r_k$  is related to the bandwidth of the resonance frequency. So, let us say system let us say I have observed the speech signal. I found it has three formants:  $F_1$ ,  $F_2$ , and  $F_3$ .  $F_1$ ,  $F_2$  and  $F_3$ ; there are three forms in the speech.

This is the frequency transform of the speech signal. So, this is the output frequency representation. So, I want to know how many poles there are in the system in the  $V(z)$ . So, as I said, 1 complex conjugate pair is related to one formant. So,  $\theta_1$  is related to one formant  $F_1$ ;  $\theta_2$  will be related to  $F_2$  and  $\theta_3$  will be related to  $F_3$ .

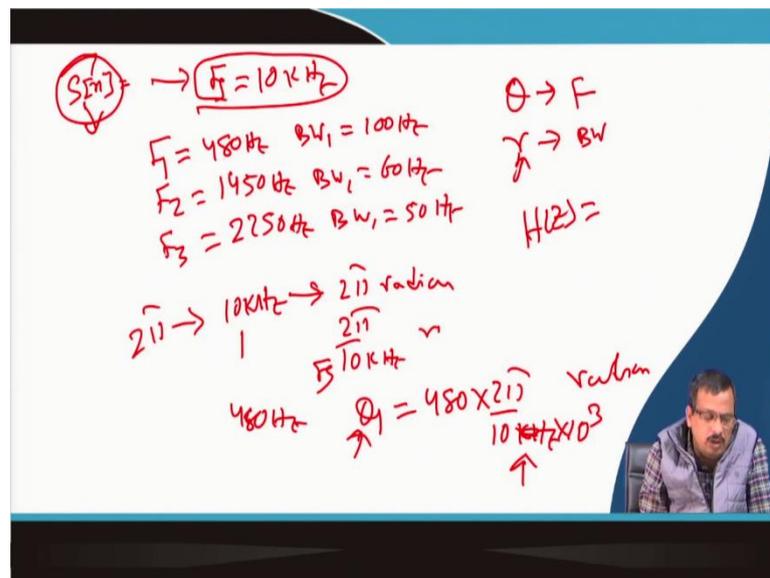

So, if I say how many complex how many complex poles are there 3 into 2, how many complex conjugate pairs are there 3 pairs? Now, suppose I measure the frequency of this formant frequency resonant frequency. So, let us know if this is around 500 hertz. So, how is this related to the  $\theta$ ?

(Refer Slide Time: 24:04)

So, I give a complete example. Let us say ah, I will take a slide, I will give you the problem, and then I solve it.

(Refer Slide Time: 24:22)

Let us say I said the problem looks like this. Let us say that I have a speech signal. Let us say I have a speech signal and signal time to speech signal is nothing, but let us say  $S[n]$ ;  $S[n]$  is the speech signal which has a sampling frequency of  $F_s$ ;  $F_s$  is equal to 10 kilohertz ok.

So, I have a digital signal. It may be a speech, let us say, speech, and it has a sampling frequency of 10 kilohertz. Now, after analyzing the signal, I found  $S[n]$  has a formant frequency  $F_1$  is related to 48 hertz, and first formant has a bandwidth this bandwidth is equal to 100 hertz.

Then I have an  $F_2$ , which is related to, let us say, for 50 hertz, and bandwidth is equal to, let us say, 60 hertz, and I have an  $F_3$ , which is related to, let us say, 2250 hertz and bandwidth is equal to, let us say 50 hertz. Can I derive the transfer function of vocal cords during the production of  $S[n]$ ? How do I derive the transfer function of the vocal cords during the production of  $S[n]$ ; that is my problem.

So, how do I solve it very easily? So, what I said is that  $\theta$  is related to the formant frequency, and  $r$  is related to the bandwidth. So, as you know the discrete in the first class, I have said the normalized discrete frequency. If the sampling frequency is equal to 10 kilohertz, then 10 kilohertz, then I know that the maximum rate of oscillation is  $2\pi$ . So,  $2\pi$  corresponds to 10 kilohertz. On the other hand, I can say 20 kilohertz corresponds to  $2\pi$  radian.

Then 1 kilohertz corresponds to  $2\pi$  by 10 kilohertz radian or nothing, but an  $F_s$ . Then I have a  $\theta$ . I have to find out the  $\theta$  for a 480 hertz. So, I can say the  $\theta_1$  equals 480 hertz multiplied by  $2\pi$  by 10 kilohertz into 10 to the power 3 radian.

If I want to multiply, I want to get an angle. So, I can say  $\pi$  is equal to 180 degrees. I get the value of the  $\theta$  or reverse way. If I know  $\theta$ , I can calculate the formant frequency. So, if I know the  $z$  representation of the  $S[n]$  or vocal track, I can find out what is the formant frequency related to pole number 1, pole number 2, pole number 3, and vice versa, then what is bandwidth? What is the bandwidth is related to the  $r$ .

So, bandwidth is related to  $r$  is nothing, but that  $b_k$  is  $r_k$  is  $e^{-b_k}$  where  $b_k$  is the bandwidth in radian, or I can say  $b_k$  is equal to minus  $\ln$  of  $r_k$ . So, if I know  $b_k$  in radians, then I can calculate  $r$ .

So, what is given  $b_k$  is given in hertz. I have to convert it into the radian; once I know the radian in  $b_k$ , I can calculate  $r_k$  and vice versa. If I know  $r_k$ , then I calculate that transfer function. also, once I know  $\theta_k$  and  $r_k$ , I can find out the transfer function is the  $z$  domain of the vocal tract.

So, z domain representation can give me the frequency response of the system analyzing pole and zero. So, this is why it is required, pole-zero concept, as I discussed, instability in the first class of Z transforms that if the poles are at a unit circle, that means it will self an oscillatory system if the poles are within the unit circle; that means, the oscillation will die down or decay down; if the poles are outside the unit circle; that means, oscillation is gradually going up.

So, based on that, I can find out the stability of the Z transform, and I can also find out the stability of the system. So, if the system wants to be stable, all poles must be on the inside of the unit circle. The unit circle means  $r_k$  is equal to 1 ok.

Now, if you see, then if I say that I have a pole position like this, which resonance frequency will be prominent? The prominent resonance frequency means when the  $r_k$  value tends to 1 because it is constant oscillation will be there unless it dies down.

So, if the  $r_k$  value tends to 0, then oscillation will initially die down. So, when I say the poles are at zero position,  $z$  equal to 0 is a pole. What is the contribution of this? The contribution of this is that when the poles are at the zeroth position, oscillation is there, but the  $r_k$  value is equal to zero.

So, if the  $r_k$  value is equal to 0, it means bandwidth is equal to 0. So, I get an infinite power at a particular frequency at the resonance frequency, but when the  $r_k$  value is not 0, I get a bandwidth of the formant or resonance ok.

So, this is the concept of pole and zero, and that is why I have to do the Z transform. Let us have a given example; I think not this 1. Let us say, 1 example I may be like this. Let us say I take an another slide.

(Refer Slide Time: 31:23)

$$y[n] = -0.5y[n-2] + 2y[n-1] + 5x[n] + 3x[n-1]$$

$$Y(z) = -0.5Y(z)z^{-2} + 2Y(z)z^{-1} + 5X(z) + 3X(z)z^{-1}$$

$$Y(z)[1 + 0.5z^{-2} - 2z^{-1}] = X(z)[5 + 3z^{-1}]$$

$$H(z) = \frac{Y(z)}{X(z)} = \frac{5 + 3z^{-1}}{1 + 0.5z^{-2} - 2z^{-1}} = \frac{5z^2 + 3z}{z^2 + 0.5 - 2z}$$

So, suppose I told you to derive the transfer function of an LTI system which is expressed in a differential equation

$$y[n] = -0.5y[n - 2] + 2y[n - 1] + 5x[n] + 3x[n - 1]$$

This is my differential equation representation of the  $y[n]$  to derive the transfer function of this system. The system that produces  $y[n]$  finds out  $H(z)$ . So, if I want to find out  $H(z)$ ,  $H(z)$  is nothing but a  $y(z)$  by  $X(z)$ . How do I do that? I take the Z transform. So,  $Y(z)z^{-2}$  plus 2 into  $Y(z)z^{-1}$  plus 5 into  $X(z)$  plus 3 into  $X(z)z^{-1}$ .

Then, I can say plus 5 into  $X(z)$  because there is no delay. So,  $z^0$  means once plus 3 into  $X(z)$  into  $z^{-1}$  plus ok done. Now, I put the  $Y$  on this side. So,  $Y(z)$  plus 0.5  $Y(z)$  into  $z^{-2}$  - 2  $Y(z)$  into  $z^{-1}$  is equal to 5  $X(z)$  plus 3  $X(z)$  into  $z^{-1}$ .

Now, I take  $Y(z)$ . So, that is nothing, but a 1 plus 0.5  $z^{-2}$  - 2  $z^{-1}$  is equal to  $X(z)$  5 plus 3  $z^{-1}$ . Now, if I say  $Y(z)$  by  $X(z)$  is equal to 5 plus 3 to the power  $z^{-1}$  divided by 1 plus 0.5  $z^{-2}$  - 2 into  $z^{-1}$  ok. So, this is the transfer function  $H(z)$ .

Now, if I say how many poles are there, 2. How many zeros are there I can make it positive also. So, if I want to make it positive, so,  $z^2$  to the power. So, if I multiply by  $(z^2)$  to the power 2, both sides are upper and lower.

So, I can say  $(z)$  to the  $z^2$  multiplied by  $(z)^2$  both. So,  $5z^2$  plus  $3z$  divided by  $z^2$  plus  $0.5z^{-1}$ , I can make it positive  $z$  ok. So, this is the  $z$  transform representation of the transfer function ok.

**Problem:**  
Given the sequence,  $x[n] = u[n]$ , find the  $z$ -transform of  $x[n]$

**Solution:**  
From the definition of the  $z$ -transform:  

$$X(z) = \sum_{n=0}^{\infty} u[n]z^{-n} = \sum_{n=0}^{\infty} (z^{-1})^n = 1 + (z^{-1}) + (z^{-1})^2 + \dots$$
 we know,  $1 + r + r^2 + \dots = \frac{1}{1-r}$  when  $|r| < 1$ .  
 Therefore,  $X(z) = \frac{1}{1-z^{-1}} = \frac{z}{z-1}$  When  $|z^{-1}| < 1 \Rightarrow |z| > 1$

Now, I have some problems which is related to the  $z$  transform I will discuss, and then I will end this class because this class is related to the. So, I have already covered the  $z$  transform. So, that is why some problem I will discuss let us say that given in sequence  $x[n]$  equal to  $u[n]$ , you know what is  $u[n]$ ;  $u[n]$  is in the unit step function; that means, at any  $N$  greater than equal to 0 then all  $r \geq 1$  so, this is  $u[n]$ .

Now, if I want to take the  $z$  transform of  $x[n]$   $X(z)$ , I know this  $N$  is equal to 0 to infinity because on this side, it is 0. So, I do not take  $N$  equal to  $-\infty$  to infinity; I take  $N$  equal to 0 to  $u[n]z^{-N}$ .

So, I can say  $(z)^{-1}$  into  $n$ . So, as a series, if it is series, you know that  $r^2 + 1 + r + r^2 + r^3 + \dots + r^n$  is equal to  $1 + r$ . So, I can say  $X(z)$  is equal to  $1 + r^{-1}$ . So, I can say  $-1$  means  $1$  by  $(z)$ . So,  $z$  by  $(z-1)$ , then what is the ROC region of convergent for which  $X(z)$  is not infinite? Here is another point for every pole  $X(z)$  is infinite.

So, that is why the poles are not within the convergent of the  $z$  transforms poles are outside of the region, or I can say the poles are not included inside the ROC poles are not included

inside the ROC understand. So, I can find out which X (z) is finite, which is the region of convergence, and that is ok.

**Problem:**  
Consider the exponential sequence,  $x(n) = a^n u(n)$ , find the z-transform of  $x(n)$ .

**Solution:**  
From the definition of the z-transform

$$X(z) = \sum_{n=0}^{\infty} a^n u(n) z^{-n} = \sum_{n=0}^{\infty} (az^{-1})^n = 1 + (az^{-1}) + (az^{-1})^2 + \dots$$

Since this is a geometric series Therefore,

$$X(z) = \frac{1}{1 - az^{-1}} = \frac{1}{1 - \frac{a}{z}} = \frac{z}{z - a}$$

that will converge for,  $X(z) = \frac{z}{z - a}$  for  $|z| > |a|$

Region of Convergence

CEES57, Dr. Nassim Alimmar, King Saud University 13

So, that way, we can solve another problem. Let us say consider  $X_n$  is equal to  $a^n$ . So, if there is a constant multiplication  $a$  to the power  $n$  same problem, I multiply by a constant. So, it is nothing, but a so;  $a$  will be multiplied region of convergent I can calculate ok. So, it is  $a/(1 - a)$  ok.

**Z-Transform Table**

Line No.	$x(n), n \geq 0$	z-Transform $X(z)$	Region of Convergence
1	$x(n)$	$\sum_{n=0}^{\infty} x(n)z^{-n}$	
2	$\delta(n)$	1	$ z  > 0$
3	$an(n)$	$\frac{az}{z-1}$	$ z  > 1$
4	$na(n)$	$\frac{z}{(z-1)^2}$	$ z  > 1$
5	$n^2u(n)$	$\frac{z(z+1)}{(z-1)^3}$	$ z  > 1$
6	$a^n u(n)$	$\frac{z}{z-a}$	$ z  >  a $
7	$e^{-an}u(n)$	$\frac{z}{z - e^{-a}}$	$ z  > e^{-a}$
8	$na^n u(n)$	$\frac{az}{(z-a)^2}$	$ z  >  a $
9	$\sin(an)u(n)$	$\frac{z \sin(a)}{z^2 - 2z \cos(a) + 1}$	$ z  > 1$
10	$\cos(an)u(n)$	$\frac{z[z - \cos(a)]}{z^2 - 2z \cos(a) + 1}$	$ z  > 1$
11	$a^n \sin(bn)u(n)$	$\frac{[a \sin(b)]z}{z^2 - [2a \cos(b)]z + a^2}$	$ z  >  a $
12	$a^n \cos(bn)u(n)$	$\frac{[z - a \cos(b)]z}{z^2 - [2a \cos(b)]z + a^2}$	$ z  >  a $
13	$e^{-an} \sin(bn)u(n)$	$\frac{[e^{-a} \sin(b)]z}{z^2 - [2e^{-a} \cos(b)]z + e^{-2a}}$	$ z  > e^{-a}$
14	$e^{-an} \cos(bn)u(n)$	$\frac{[z - e^{-a} \cos(b)]z}{z^2 - [2e^{-a} \cos(b)]z + e^{-2a}}$	$ z  > e^{-a}$

$\frac{Az}{z-P} + \frac{A'z}{z-P^*}$  where  $P$  and  $A$  are complex constants defined by  $P = |P| \angle \theta, A = |A| \angle \phi$

2|A||P|^n cos(nθ + φ)u(n)

14

Similarly, those are the tables where you can get the table; table of z transform, which is the table for which z transform is already given using that table when we go for the z transform, we can use this table, or when we go for the inverse z transform we can use this table.

(Refer Slide Time: 38:05)

**Problem:**  
Find the z-transform for each of the following sequences:

a.  $x(n) = 10\sin(0.25\pi n)u(n)$       b.  $x(n) = e^{-0.1n}\cos(0.25\pi n)u(n)$

**Solution:**

a. From line 9 in the Table:  $X(z) = 10Z(\sin(0.2\pi n)u(n))$   

$$= \frac{10\sin(0.25\pi)z}{z^2 - 2z\cos(0.25\pi) + 1} = \frac{7.07z}{z^2 - 1.414z + 1}$$

b. From line 14 in the Table:  $X(z) = Z(e^{-0.1n}\cos(0.25\pi n)u(n)) = \frac{z(z - e^{-0.1}\cos(0.25\pi))}{z^2 - 2e^{-0.1}\cos(0.25\pi)z + e^{-0.2}}$   

$$= \frac{z(z - 0.6397)}{z^2 - 1.2794z + 0.8187}$$

Let us say another 1 find the z transform for the X n is equal to you can do it 10 sin 0.5π n u[n] line number 9, what is line number 9; sin of a n u[n] is this 1 is the z transform.

So, you just put the value, you can get this z transform, or you can do it you can do it z to the n equal to -n infinity, put that value, and find out the z transform ok. So, that is the complete z transform we have covered. Now, we go for the inverse z transform in the next class.

Thank you.
