**Interpolation and Approximation (Continued)**

In our previous lectures we have derived various forms of interpolating polynomials to fit a given data which consists of an abscissa and the corresponding ordinate at  $n$  plus 1 points. Now we derived the various forms in the sense we have Lagrange interpolation, divided difference interpolation and if it as a equispaced data we have the Newton's formulas of backward forward formulas and if now, if you add for this data one more item like the slope of the function that is representing the given data, then we can have a different type of polynomial all together, so let us now consider data of this particular form.

(Refer Slide Time: 01:42)

abscissas  $x_0 \quad x_1 \quad \dots \quad x_n$   
 ordinates  $f_0 \quad f_1 \quad \dots \quad f_n \rightarrow n+1$  values  
 Slopes  $f'_0 \quad f'_1 \quad \dots \quad f'_n \rightarrow n+1$  values  
 $\Rightarrow 2n+2$  values  
 $\therefore$  A polynomial of degree  $\leq 2n+1$  can be fitted.  
Hermite Interpolation  
 $P(x_i) = f(x_i), \quad P'(x_i) = f'(x_i); \quad i=0,1,\dots,n$   

$$P(x) = \sum_{i=0}^n A_i(x) f(x_i) + \sum_{i=0}^n B_i(x) f'(x_i)$$

Polynomial of degree  $2n+1$

The data that is given to us shall be the abscissas that we take it as  $x_i$ , this this is your  $x_0, x_1$ , so on  $x_n$ , then we have the ordinates given to us as  $f_0, f_1, f_n$ . Now this was the data that we considered earlier, let us now add to this slope at these points also, so let us also consider the case when we have slopes also at this, which we shall write it as  $f$  prime at 0,  $f$  prime at 1, so on  $f$  prime at  $n$ . Now what type of interpolating polynomial can we derive for this particular data, now if you look at this number of ordinates that we have, we have  $n$  plus 1 values of this ordinates. Now if you consider simply the data  $x_i \quad f_i$  that is this data, then we were able to write down a polynomial of degree less than is equal to  $n$  which fits this data exactly. Now we have

Hence this implies that we can fit a polynomial of degree less than or equal to  $2n + 1$  for this data, therefore a polynomial of degree less than or equal to  $2n + 1$  can be fitted and the polynomial which does this job, we shall call it as Hermite interpolation, so we shall call it as Hermite interpolation. That means we want to construct a polynomial  $P$ , such that  $p$  at  $x_i$  is equal to  $f$  at  $x_i$  and  $P$  prime at  $x_i$  is  $f$  prime at  $x_i$  for  $i$  is equal to  $0, 1, \dots, n$ . Now we shall follow the procedure that we have adopted in deriving the Lagrange interpolation, now the interpolating polynomial must be, now a linear combination of these ordinates and these slopes also, that means I must be able to write down the polynomial  $P(x)$  is equal to summation of  $i$  is equal to  $0$  to  $n$ , some  $A_i(x) f$  of  $x_i$  plus summation  $0$  to  $n$   $B_i(x) f$  prime at  $x_i$ , so the polynomial should be a linear combination of these ordinates,  $n + 1$  ordinates and  $n + 1$  slopes. Now since this polynomial is of degree less than or equal to  $2n + 1$ ,  $A_i(x)$  and  $B(x)$  must be polynomials of degree  $2n + 1$ , these are polynomials of degree  $2n + 1$ . Since this polynomial should fit this data exactly, we can find out the conditions under which this approximation is possible for us.

$$P_{n,j}(x_j) = \sum_{i=0}^n A_i(x_j)f(x_i) + \sum_{i=0}^n B_i(x_j)f'(x_i)$$
$$\equiv f(x_j) \qquad P(x_j) = f(x_j)$$
$$\left. \begin{aligned} A_i(x_j) &= 1, i=j \\ &= 0, i \neq j \\ A'_i(x_j) &= 0, \text{for all } i, j \end{aligned} \right\} \quad \left. \begin{aligned} B_i(x_j) &= 0, \text{for all } i, j \\ B'_i(x_j) &= 1, \text{for } i=j \\ &= 0, \text{for } i \neq j \end{aligned} \right\}$$
$$P'(x_j) = \sum_{i=0}^n A'_i(x_j)f(x_i) + \sum_{i=0}^n B'_i(x_j)f'(x_i)$$
$$\equiv f'(x_j) \qquad P'(x_j) = f'(x_j)$$

Ex 2 : Polynomials of degree 2 n .  $\ell_i(x_j) = 0, i \neq j$   
 $= 1, i=j$

2

You write it in the 2 columns, so we shall fill up the remaining data over here. Now let us look at  $A_i(x_j)$ , this should be equal to  $f(x_j)$  therefore all of them would be 0 except when the both suffixes are same, so you will have here  $A_i(x_i)$  is equal to 1  $A_i(x_j)$  is equal to 0, for  $i$  is equal to  $j$ , is equal to 0 for  $i$  not equal to  $j$ . Then this will give us simply 1 into  $f$  of  $x_j$  so it will be identically equal to this.

Now we shall fill up here, I will just leave some space over here. Let us differentiate this and set  $x_j$  here, so I am differentiating this particular polynomial and then to it, so it will give us derivative of  $A_i$  and here it will give derivative of  $B_i$ , these are constants so only derivative of  $A_i$  and  $B_i$  will come, so that we can write it as summation  $i$  is equal to 0 to  $n$ ,  $A_i$  prime  $x_j f(x_i)$  plus summation  $i$  is 0 to  $n$ ,  $B_i$  prime  $x_j f$  prime at  $x_i$ . Now you can see that this should be identically equal to  $f$  prime of  $x_j$  because the interpolation condition is  $P$  dash  $x_j$  is equal to  $f$  prime of  $x_j$ . Therefore this should be identically equal to this, therefore this implies that there cannot be any ordinates here that means this  $A_i$  prime  $x_j$  will be 0 for all  $i \neq j$ , so that means I can now write here  $A_i$  prime  $x_j$  is equal to 0 for all  $i \neq j$ . Whether it is equal or not equal, in all the cases the value of  $A_i$  prime  $x_j$  will be equal to 0 and  $B_i$  prime  $x_j$  will be equal to 1 when  $i$  is equal to  $j$  and it will be zero for  $i$  not equal to  $j$  because this should produce  $f$  prime at  $x_j$ . Therefore we will have here  $B_i$  prime  $x_j$  is equal to 1 for  $i$  is equal to  $j$ , is equal to 0 for  $i$  not equal to  $j$ .

Now we need to construct, now  $A_i$  and  $B_i$  just as we have done in the Lagrange interpolation by looking at the property of  $A_i$  and its derivative,  $B_i$  and its derivative. Now we remember that  $A_i$  and  $B_i$  are polynomials of degree  $2n + 1$ , so what we will do it, we shall take advantage of the Lagrange fundamental polynomials, which are polynomials of degree  $n$ . So if I consider  $l_i$  square, this will be polynomial of degree  $2n$ , polynomials of degree  $2n$  and this satisfies our properties that  $l_i(x_j)$  is equal to 1 for  $i$  is equal to  $j$ ,  $l_i(x_j)$  is equal to 0 for, we know this property that  $l_i(x_j)$  is equal to 0 for  $i$  not equal to  $j$ , is equal to 1 for  $i$  equal to  $j$ . Because of this property which is inbuilt for A construction of this, I shall take, use this  $l_i$  square Lagrange fundamental polynomials in building this  $A_i$  and  $B_i$ .

(Refer Slide Time: 11:07)

$$\begin{aligned}
 \text{Let } A_i(x) &= [a_i + b_i(x-x_i)] l_i^2(x) & : 2n+1 \\
 B_i(x) &= [c_i + d_i(x-x_i)] l_i^2(x) & : 2n+1 \\
 A_i(x_i) &= [a_i + 0] \cdot 1 = 1 & : a_i = 1 \text{ for all } i \\
 A_i'(x) &= [a_i + b_i(x-x_i)] 2 l_i(x) l_i'(x) \\
 &\quad + b_i l_i^2(x) \\
 A_i'(x_i) &= [a_i + 0] 2 \cdot 1 \cdot l_i'(x_i) + b_i \cdot 1 \\
 &= 0 \\
 b_i &= -2 a_i l_i'(x_i) = -2 l_i'(x_i)
 \end{aligned}$$

So what I would do since  $l_i$  square is a polynomial of degree  $2n$  and  $A_i, B_i$  are only polynomials of degree  $2n$  plus 1, I need to multiply this only by linear polynomial that means we shall assume that let  $A(x)$  is equal to suffix  $i$ , some suffix  $i$  you put it,  $[a_i$  plus  $b_i$  into  $(x$  minus  $x_i)$ ]  $l_i$  square  $x$  and  $B_i(x)$  is equal to some  $c_i$   $d_i$   $(x$  minus  $x_i)$   $l_i$  square  $x$ . Now  $l_i$  square is a polynomial of degree  $2n$ , I am now multiplying this by linear polynomial of the special form which I have taken it in this particular form because it is easy for us to find the constants in that case. Now this is a polynomial of degree  $2n$  plus 1 and this is also a polynomial of degree  $2n$  plus 1.

If we are able to find uniquely  $a_i, b_i, c_i, d_i$  from the data that we have, then we have what we have written in the formula is correct. So let us try to find that one, let us look at, let us just put this condition over here. We shall now determine the parameters  $a_i, b_i, c_i$  and  $d_i$  using the conditions on  $a_i$  and  $b_i$  which we have obtained earlier as this, where  $A_i(x_j)$  is equal to 1 for  $i$  is equal to  $j$ , it is 0 for  $i$  not equal to  $j$ . Similarly  $A_i'$  prime  $x_j$  is equal to 0 for all  $i$  and  $j$  and similarly the conditions on  $B_i$ . We shall apply these conditions one after the other to determine the constants  $a_i, b_i, c_i$  and  $d_i$ . Let us first of all substitute  $x_i$  in  $A_i(x)$ , so if I substitute  $x$  is equal to  $x_i$ , I get here  $a_i$  plus 0, this is 0, then I get  $l_i(x_i)$  is 1 therefore  $l_i(x)$  square is equal to 1 and this should be equal to 1,  $a_i$  is equal to 1 for all  $i$ . Now we have determined one of the parameters  $a_i$  in this capital  $A_i$ . Now let us differentiate  $A_i$  therefore I will get  $A_i'$  prime of  $x$  is equal to, it is a product of 2 functions, so let us write this product as  $[a_i$  plus  $b_i$  into  $(x$  minus  $x_i)$ ] derivative of this is 2 times  $l_i(x)$   $l_i'$  prime  $x$  plus the derivative of this gives us simply  $b_i$  into  $l_i$  square of  $x$ . Now we have the condition that  $A_i'$  prime  $x_j$  is equal to 0 for all  $i, j$ .

Let us now substitute and see here, if I put  $A_i'$  prime  $x_i$  here, I would get here is  $a_i$  plus,  $x$  is equal to  $x_i$  that is 0, then I will have here 2 times  $l_i(x_i)$  is equal to 1, I will have  $l_i'$  prime of  $x_i$  plus  $l_i(x_i)$

is equal to 1 therefore I will have here  $b_i$  into 1 and the value of  $A_i$  prime  $x_i$  is equal to 0 that is the condition that we have here, that  $A_i$  prime  $x_j$  is equal to zero for all  $i$  and  $j$ . Therefore I can determine  $b_i$  from here therefore I will have  $b_i$  is equal to minus 2 times  $a_i$  into  $l_i$  prime of  $x_i$  but  $a_i$  is equal to 1 therefore I will get 2 times  $l_i$  prime of  $x_i$ . Now similarly we shall apply the conditions on  $b_i$  to determine the constant  $c_i$  and  $d_i$ .

(Refer Slide Time: 15:22)

$$\begin{aligned}
 B_i(x_i) &= [c_i + 0] l_i^2(x_i) = c_i \cdot 1 = 0 \\
 c_i &= 0 \text{ for all } i \\
 B_i'(x) &= [c_i + d_i(x - x_i)] 2 l_i(x) l_i'(x) \\
 &\quad + d_i l_i^2(x) \\
 B_i'(x_i) &= [c_i + 0] 2 l_i(x_i) l_i'(x_i) \\
 &\quad + d_i \cdot 1 \\
 &= 1 \qquad \therefore d_i = 1 \text{ for all } i
 \end{aligned}$$

Now let us substitute  $x$  is equal to  $x_i$  in  $B_i$  of  $x$ , so if I have put  $B_i(x_i)$  that gives me, I am now substituting here in this the, I am substituting  $x$  is equal to  $x_i$  in this, so let us keep this slide here, this is  $[c_i \text{ plus } 0] l_i$  square of  $x_i$  and this is equal to 1 therefore this gives us  $c_i$  into 1 but this is equal to 0, this is equal to 0. Therefore we get  $c_i$  is equal to 0 for all  $i$ . Then let us differentiate  $B_i(x)$ , let us differentiate  $B_i(x)$  from here, so I will have here  $B_i$  prime of  $x$  is equal to  $[c_i \text{ plus } d_i \text{ into } (x \text{ minus } x_i)]$  derivative of  $l_i$  square is 2 times  $l_i(x)$   $l_i$  prime of  $x$  plus derivative of the first one gives us  $d_i$  into  $l_i$  square of  $x$ . Now use the condition that  $B_i$  prime  $x_i$  is equal to 1, so if I put  $B_i$  prime of  $x_i$  here, I get here  $c_i \text{ plus this is } 0$ , that is 2 times  $l_i(x_i)$   $l_i$  prime of  $x_i$  plus  $d_i$  into 1. Now  $B_i$  prime of  $x_i$  is equal to 1 therefore this is equal to 1. Now  $c_i$  is equal to 0 therefore this bracket goes off and we have simply  $d_i$  therefore we obtain  $d_i$  is equal to 1 for all  $i$ . Now we have determined all the 4 constants. So we can now substitute in the expression for  $A_i(x)$  and  $B_i(x)$  that is this expression  $A_i(x)$  and this.

(Refer Slide Time: 17:43)

$$\begin{aligned}
 A_i(x) &= [1 - 2(x - x_i) l_i'(x_i)] l_i^2(x) \\
 B_i(x) &= [(x - x_i)] l_i^2(x) \\
 P(x) &= \sum_{i=0}^n A_i(x) f(x_i) + \sum_{i=0}^n B_i(x) f'(x_i) \\
 \text{Hermite interpolating polynomial} \\
 \text{of degree } \leq 2n+1.
 \end{aligned}$$

Let us substitute it and see what we get, we get  $A_i(x)$  is equal to, is equal to  $A$  [1 minus 2 times  $(x - x_i)$  into  $l_i'$  prime of  $x_i$ ] into  $l_i$  square of  $x$ . Now this we have obtained it because we have got here  $a_i$  is equal to 1 and we have obtained  $b_i$  is equal to minus 2 times  $a_i$   $l_i'$  prime of this  $x_i$ , so we have substituted for  $b_i$  and this is  $(x - x_i)$  over here, therefore this is the expression in the brackets for  $A_i(x)$  and outside the bracket we have  $l_i$  square  $x$ . Similarly we get for  $B_i(x)$ , this is equal to, now  $c_0$  is 0 and  $d_i$  is equal to 1 therefore I simply get  $(x - x_i)$  into  $l_i$  square of  $x$  and therefore for the required polynomial,  $P(x)$  is equal to summation of  $i$  is equal to 0 to  $n$   $A_i(x) f$  of  $x_i$  plus summation  $i$  is equal to 0 to  $n$   $B_i(x)$  of  $f$  prime of  $x_i$ .

We call this as the Hermite interpolating polynomial, we call this as the Hermite interpolating polynomial, interpolating polynomial, which is of degree less than or equal to  $2n + 1$ . Now to compute this interpolating polynomial we need to determine  $l_i(x)$ , I need to determine  $l_i'$  prime then substitute the values over here, determine my  $A(x)$   $B_i(x)$  from here, sum them up, simplify it to finally arrive at the polynomial of degree  $2n + 1$  or less than  $2n + 1$  and that represents the interpolating polynomial which fits exactly that given data.

(Refer Slide Time: 20:23)

Example Construct an interpolating polynomial that fits the data

$x$	1	2
$f(x)$	2	17
$f'(x)$	4	32

$$l_0(x) = \frac{x - x_1}{x_0 - x_1} = \frac{x - 2}{1 - 2} = 2 - x, \quad l_0'(x) = -1$$

$$l_1(x) = \frac{x - x_0}{x_1 - x_0} = \frac{x - 1}{2 - 1} = x - 1, \quad l_1'(x) = 1$$

Set  $i = 0$  in  $A_i(x)$ . We get

$$A_0(x) = [1 - 2(x - x_0) l_0'(x_0)] l_0^2(x)$$

$$= [1 + 2(x - 1)] (2 - x)^2$$

$$= (2x - 1) (2 - x)^2$$

Now let us take an example on this, let me write the example. Now construct an interpolating polynomial that fits the data  $x$ , let us take only 2 points,  $f(x)$  is 2 values 2 ordinates and the slopes  $f'$  prime  $x$  is 4 and 32. Now we need to first of all write down our Lagrange fundamental polynomials  $l_i(x)$ , there only 2 data points therefore we will have  $l_0(x)$  is equal to  $(x \text{ minus } x_1)$  upon  $(x_0 \text{ minus } x_1)$  that is  $(x \text{ minus } 2)$  divided by  $1 \text{ minus } 2$  that is minus 1, which is your  $2 \text{ minus } x$  and we need the derivative also, let us differentiate it  $l_0$  of  $x$  also, let's write down  $x$  also, that is equal to minus 1. Here it is a linear polynomial therefore derivative is a constant otherwise this would not be a constant, if we take more data points it will be a function of  $x$ .

Now let us write down  $l_1(x)$ , this is  $(x \text{ minus } x_0)$  divided by  $(x_1 \text{ minus } x_0)$  that is  $(x \text{ minus } 1)$  divided by 1 that is your  $(x \text{ minus } 1)$ . We need its derivative also, let us differentiate it, this is equal to 1. Now we need to find the quantities  $A_0, A_1, B_0, B_1$  to use this particular expression. Now we set  $i$  is equal to 0 in this to get  $A_0(x)$ , now we shall say, set  $i$  is equal to 0 in  $A_i(x)$  then we get  $A_0(x)$  is equal to, now we are setting  $i$  is equal to 0, therefore I will get here  $x_0$ , this is  $l_0$  prime  $x_0$ , this is  $l_0$  square  $x$ , so I will get here  $[1 \text{ minus } 2(x \text{ minus } x_0) l_0' \text{ prime } x_0]$  into  $l_0$  square of  $x$ . Now I will substitute the values of  $l_0$  prime  $x_0$  is minus 1,  $l_0(x)$  is equal to  $(2 \text{ minus } x)$ , therefore I will get here 1, this is negative sign so I will write it as plus 2  $(x \text{ minus } x_0)$  is 1,  $l_0$  square is  $(2 \text{ minus } x)$  whole square. We can simplify and write this as  $(2x \text{ minus } 1)$  into  $(2 \text{ minus } x)$  whole square.

(Refer Slide Time: 23:51)

Set  $i=1$  in  $A_i(x)$ . We get

$$A_1(x) = [1 - 2(x - x_1) l_1'(x_1)] l_1^2(x)$$

$$= [1 - 2(x - 2) \cdot 1] (x - 1)^2$$

$$= [5 - 2x] (x - 1)^2$$

$$B_0(x) = [x - x_0] l_0^2(x)$$

$$= (x - 1) (2 - x)^2$$

$$B_1(x) = (x - x_1) l_1^2(x)$$

$$= (x - 2) (x - 1)^2$$

Now set  $i$  is equal to 1 in  $A_i(x)$ , we get, I am setting  $i$  is equal to 1 so I will have here  $x_1$   $l_1$  prime  $x_1$   $l_1$  square  $x$ , therefore I will get here  $A_1(x)$  is  $[1$  minus  $2$  times  $(x$  minus  $x_1)$   $l_1$  prime  $x_1]$  into  $l_1$  square of  $x$ . Now  $x_1$  is equal to  $2$ ,  $l_1$  prime of  $x_1$  is  $1$  and  $l_1(x)$  is  $(x$  minus  $1)$ , therefore I get here  $1$  minus  $2$  into  $(x$  minus  $2)$   $l_1$  prime of  $x_1$  is  $1$ , so I will have this as  $1$  and  $l$  square of  $x$  is  $(x$  minus  $1)$  whole square, that is  $(x$  minus  $1)$  whole square. Therefore this I will get it as  $4$  plus  $1$ ,  $[5$  minus  $2x]$  into  $(x$  minus  $1)$  whole square.

Now set  $i$  is equal to  $0$  in  $B_i(x)$ , therefore I will get  $B_0(x)$  is equal to  $[x$  minus  $x_0]$  into  $l_0$  square  $x$ . Again our  $l_0$  is  $(2$  minus  $x)$  therefore this will simply give us  $(x$  minus  $1)$  into  $(2$  minus  $x)$  whole square. Now set again  $i$  is equal to  $1$  in  $B_i(x)$  therefore I will get  $B_1$  is  $(x$  minus  $x_1)$   $l_1$  square  $x$ , therefore I get  $B_1(x)$  is  $(x$  minus  $x_1)$   $l_1$  square of  $x$ ,  $x_1$  is  $2$  therefore I get, here I get  $x_1$  is  $2$  and we have got here  $l_1(x)$  is  $(x$  minus  $1)$ , therefore this is equal to  $(x$  minus  $1)$  whole square. Now I got this 4 quantities and which we can substitute now in  $P(x)$  to get our polynomial.

(Refer Slide Time: 26:25)

Handwritten text on a greenboard:

Hermite interpolating polynomial is

$$\begin{aligned}
 P(x) &= A_0(x) f(x_0) + A_1(x) f(x_1) \\
 &\quad + B_0(x) f'(x_0) + B_1(x) f'(x_1) \\
 &= (2x-1)(2-x)^2(2) + (5-2x)(x-1)^2(17) \\
 &\quad + (x-1)(2-x)^2(4) + (x-2)(x-1)^2(32) \\
 &= (8x-6)(2-x)^2 + (21-2x)(x-1)^2
 \end{aligned}$$

Therefore the required Hermite interpolating polynomial is,  $P(x)$  is equal to  $A_0(x)$   $f$  of  $x_0$  plus  $A_1(x)$   $f$  of  $x_1$  plus  $B_0(x)$   $f$  prime of  $x_0$  plus  $B_1(x)$   $f$  prime of  $x_1$ . Now we can substitute the values that we have obtained earlier that gives us  $(2x - 1)$  into  $(2 - x)$  whole square into 2 plus  $(5 - 2x)$  into  $(x - 1)$  whole square into 17 plus  $(x - 1)$  into  $(2 - x)$  whole square into 4 plus  $(x - 2)$  into  $(x - 1)$  whole square into 32. Now we can simplify it and we get the result as  $(8x - 6)$  into  $(2 - x)$  whole square plus  $(21 - 2x)$  into  $(x - 1)$  whole square. Now you can easily verify that this fits our data exactly.

Now before we proceed further we should make some comments or a little word of caution on using the interpolating polynomials. If a large data is given say  $n + 1$  points, we can construct a polynomial of degree less than or equal to  $n$  to fit the data but the data that we have got is usually from an experiment or from some observations, therefore if you are given a, say 4 plus accuracy table, the last digit of this is always due to round off errors because you are rounding it off is there. Now if you are constructing a polynomial of degree 99 say for the data given as 100 data is given, if you are constructing polynomial of degree 99, we are now using the multiplications of these ordinates by numbers which are the coefficients in the polynomial. Therefore the round off error that is there in each data item gets multiplied and cumulatively the total round off error will be enormous and no experiment you can give the result exactly, therefore it is not advised and it is not used to construct higher order degree interpolating polynomial even though the data is very very large. The only alternative would be, to at the most go up to cubic or the fourth degree polynomial beyond that we do not go and hence it is possible for us to break the data into blocks, say for example if you have got, suppose we have got a data of say at the 6 points, well let us write down this data.

(Refer Slide Time: 29:54)

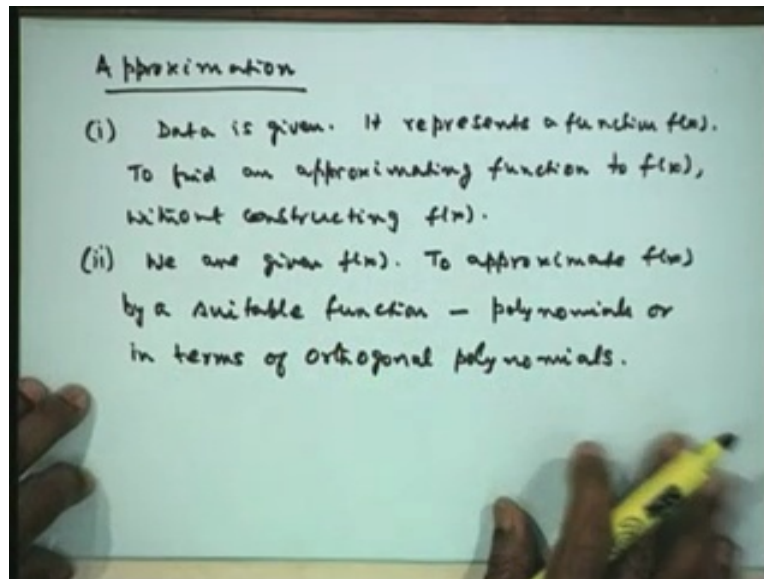

Suppose I have given the data is the seven points are given, I know that I can construct the polynomial of degree 6; if slopes are given we can construct the polynomial of degree 13 but what we are stating is in practice we should not use that. What we use it, for example I can break this into two blocks of these points, so this contains 4 points and this contains 4 points, continuously  $x_0$  to  $x_3$ , this is your  $x_0$  to  $x_3$ , this is  $x_3$  to  $x_6$ . Then I construct interpolating polynomial on each of these blocks, so construct interpolating polynomials on each of these blocks. Now in this case they are cubic polynomials, in this case they are cubic polynomials. Then we shall call such interpolation as piecewise interpolation, so we shall call this as piecewise interpolation.

It has all the properties of the interpolating polynomial that we have discussed here except that the entire data is being made into small blocks and on each of them we are constructing a cubic polynomial, for example four data points, if we are taking three data points we will have a quadratic, quadratic, quadratic. Therefore we are going to write down the interpolating polynomial as something like, for example here I would write this as  $P(x)$ ,  $P(x)$  is equal to some  $A_1(x)$  cubed plus  $B_1(x)$  squared plus  $C_1(x)$  plus  $d_1$ , for  $x_0$  less than  $x$  less than  $x_3$  and I can put equal to because we have taken the point in both it is, both of them are fitting exactly at  $x_3$  therefore continuity at  $x_3$  is available for us. This is some  $A_2(x)$  cubed plus  $B_2(x)$  square plus  $C_2(x)$  plus  $d_2$ ,  $x_3$  is less than  $x$  less than or equal to  $x_6$ , either put equal to here, equal to here, because both of them are going to be the same thing. That of course that  $P$  at  $x_3$  is equal to  $f(x_3)$ , so both of them would satisfy this. Therefore in this way we can give for the entire data, we can say that for this first block this is the polynomial, second block this is the polynomial, third block this is the polynomial and then use this piecewise interpolating polynomials for predicting the data values at any of the intermediate points. This is what we normally do in practice if you have a very huge data. Even though theoretically we construct very high degree polynomial but in

practice we shall not be using it. Now let us look at the second problem in this that is your approximation.

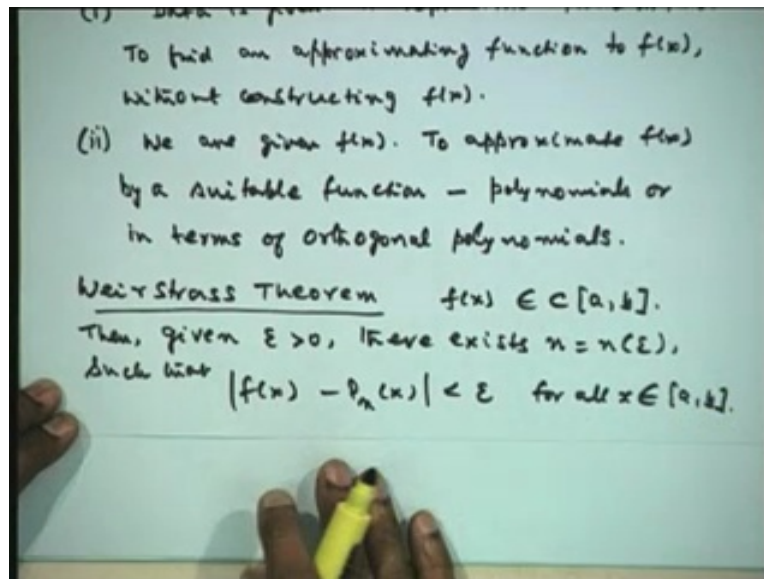

(Refer Slide Time: 33:23)

Now we mentioned earlier that the problem of approximation is of two type, one type is that data is given to us, data is given, we know that it represents a function  $f(x)$ , it represents a function  $f(x)$  but without actually constructing this function  $f(x)$ , we would like to write down an approximating polynomial or a function which approximate  $f(x)$  for this given data. Now the problem is therefore to find an approximating function, approximating function to  $f(x)$  without constructing  $f(x)$  that means we would like to construct the function without actually going through the process of interpolation.

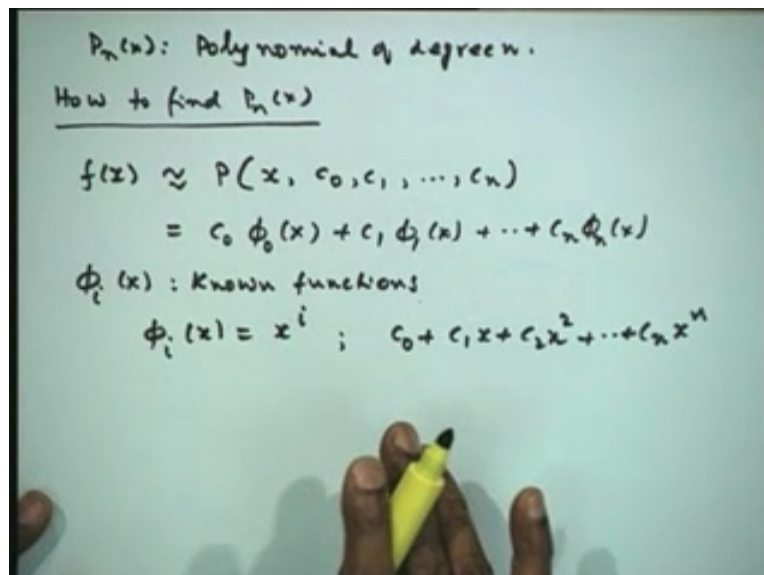

Now the second is that we are given a function  $f(x)$ , here we are given  $f(x)$ , if the problem is to approximate  $f(x)$  by a suitable function, what is this function? It could be polynomials or orthogonal polynomials; that is they are functions of polynomials or in terms of orthogonal polynomials. So that the properties of the function given to us, which was a complicated function can be studied through these polynomials because when once we write it in terms of an orthogonal polynomial, we know all the properties of the orthogonal polynomial implied there and we can use those properties to say about the behavior or any other property that we need of the given function  $f(x)$ . Now if I want to construct these two, first of all we must guarantee ourselves that such a representation in terms of polynomials or in terms of orthogonal polynomials is guaranteed for us otherwise we are not sure whether what we are obtaining is correct or not, the answer for this is, yes we have a theorem called Weierstrass theorem, which states that if we have a continuous function over interval  $[a, b]$  then we can always approximate it by a polynomial. So that is known as Weierstrass theorem, which guarantees that what we are doing is correct and we will be able to get a unique polynomial from there.

(Refer Slide Time: 36:49)

Let us define what our Weierstrass theorem is. So we have a function which is continuous, belongs to the class of continuous function over the interval  $[a, b]$ . Then the theorem states, then given an epsilon greater than 0, there exists a number  $n$  which is a function of epsilon such that  $f(x)$  minus  $P_n(x)$  is less than epsilon for all  $x$  contained in  $[a, b]$ , where  $P_n(x)$  is a polynomial of degree  $n$ .

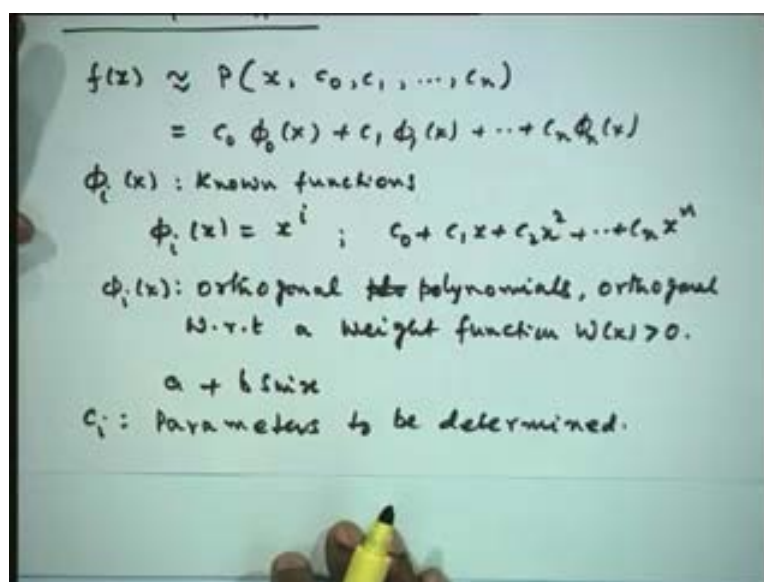

(Refer Slide Time: 37:47)

Therefore the Weierstrass theorem guarantees that we can approximate a continuous function by a polynomial of degree  $n$ , so we will take this assumption that it is possible. Then how to construct this particular function using this particular, the definition that  $f(x)$  minus  $P_n(x)$  should be less than epsilon. Now the problem is therefore is to how to find  $P_n(x)$ . What we do is, we take  $P_n(x)$  in terms of some function  $x$  that is polynomial or orthogonal polynomials whatever that we have given here, therefore  $f(x)$  will be approximating polynomial in terms of the variable  $x$  and we introduce some constants  $c_0, c_1, c_2, \dots, c_n$ ,  $c_0$  to  $c_n$  that means what we are essentially writing here is some  $c_0 \phi_0$  of  $x$  plus  $c_1 \phi_1$  of  $x$  plus so on  $c_n \phi_n(x)$ .  $\phi_i$ 's are the known functions, these  $\phi_i(x)$  are the known functions, are the known functions,  $\phi_i(x)$  are the known functions.

For example they can be taken as polynomials, I can simply take it as  $\phi_i(x)$  is equal to  $x$  to the power of  $i$ , I can take  $\phi_i(x)$  is equal to  $x$  to the power of  $i$ , that means  $\phi_0$  is 1,  $\phi_1$  is  $x$ ,  $\phi_2$  is  $x$  square that means what I am really writing here is  $c_0$  plus  $c_1(x)$  plus  $c_2(x)$  square plus so on  $c_n(x)$  to the power of  $n$  that is simply a polynomial, that is what we have this or I can take  $\phi_i(x)$  as orthogonal polynomial, orthogonal polynomials, orthogonal polynomials which are orthogonal with respect to a weight function, orthogonal with respect to, with respect to a weight function. Now what we are really talking of is the Legendre polynomials and the Chebyshev polynomials. The Legendre polynomials are orthogonal with respect to 1; weight function is 1, whereas the Chebyshev polynomials are orthogonal with respect to weight function  $1/\sqrt{1-x^2}$  upon under root  $1-x^2$ , that will come later on but we are just saying why we are introducing a  $w(x)$  here, because these orthogonal polynomials have a weight function over which they are orthogonal. Now further the  $\phi(x)$  could be any other function which represents your experiment properly, for example if in an experiment the solution of the variable is in the form of sine or a cosine wave, we can write down this as, for example I could simply write the as some  $a + b \sin x$ .

(Refer Slide Time: 41:37)

$$f(x) \approx P(x, c_0, c_1, \dots, c_n)$$

$$= c_0 \phi_0(x) + c_1 \phi_1(x) + \dots + c_n \phi_n(x)$$

$\phi_i(x)$  : Known functions

$$\phi_i(x) = x^i ; \quad c_0 + c_1 x + c_2 x^2 + \dots + c_n x^n$$

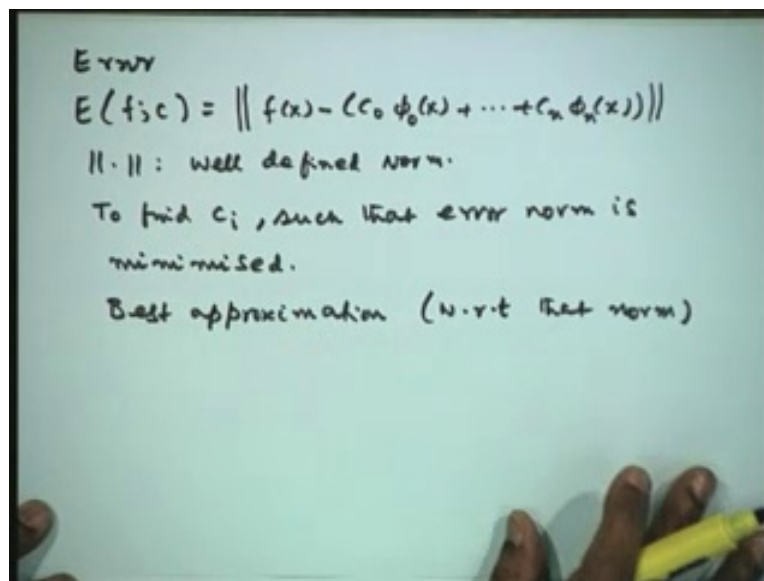

$\phi_i(x)$ : Orthogonal polynomials, orthogonal w.r.t a weight function  $w(x) > 0$ .

$a + b \sin x$

$c_i$  : Parameters to be determined.

I can take an approximation for this as,  $a + b \sin x$  but I must be able to determine the parameters  $a$  and  $b$ . Now therefore these  $c_1, c_2, c_i$ , these  $c_i$  are parameters to be determined, parameters to be determined. Now we must give the rule under which these parameters can be determined, for that we shall consider the error that is coming from here.

(Refer Slide Time: 42:20)

$E(f; c)$   
 $E(f; c) = \| f(x) - (c_0 \phi_0(x) + \dots + c_n \phi_n(x)) \|$   
 $\| \cdot \|$ : well defined norm.  
 To find  $c_i$ , such that error norm is minimised.  
 Best approximation (w.r.t that norm)

So we will take the error here, therefore the error, let us write down  $E$  of  $(f; c)$ ,  $c$  is the vector of this  $c_0, c_1, c_2, c_3$  and we will take this as norm of  $f(x)$  minus  $(c_0 \phi_0(x) + c_n \phi_n(x))$ , where this is a well defined norm, it is a one of the norms that we know, it is a well defined norm. Now therefore the problem reduces to how do you find this  $c_i$ , therefore the problem is to find  $c_i$ , to find  $c_i$  such that the error is minimized, the error should be smallest, to find  $c_i$  such that error norm is minimized. That particular approximation for which error is minimized that means that particular approximation, this approximation for which this error is minimized shall be called as the best approximation, so this shall be called as the best approximations. Of course we should qualify it as with respect to that norm which we have used, with respect to that norm. Now we have specified what we mean by this error, what are the things that we have to do, we have to find  $c_i$  such that the error norm is minimized. Now the next step we shall define is; what is norm? We have earlier given a number of definitions of norms of which we shall use two of the norms.

(Refer Slide Time: 44:32)

Error  
$$E(f; c) = \| f(x) - (c_0 \phi_0(x) + \dots + c_n \phi_n(x)) \|$$
  
 $\| \cdot \|$ : well defined norm.  
To find  $c_i$ , such that error norm is minimised.  
Best approximation (w.r.t that norm)  
Norm  
Euclidean norm  
Data:  $\|x\| = \left( \sum_{i=1}^n |x_i|^2 \right)^{1/2}$

One norm that we shall use is the Euclidean norm, Euclidean norm. Now let us define what is this Euclidean norm, let us suppose we are given a data then we shall define this norm as, norm of  $x$  is equal to summation of magnitude of  $x_i$  square to the power of half. So we are taking the summation over all the elements, magnitude of  $x_i$  square whole to the power of half.

(Refer Slide Time: 45:13)

Continuous function  $f(x)$ :  
$$\|f(x)\| = \left[ \int_a^b w(x) f^2(x) \right]^{1/2}$$
  
 $w(x)$ : weight function  $> 0$ .  
Least squares approximation.  
Uniform norm  
$$\|x\| = \max_i |x_i|$$
  
Continuous function:  $\|f(x)\| = \max_{a \leq x \leq b} |f(x)|$   
Uniform approximation.

However if we are given a continuous function  $f(x)$ , then we define the norm of  $f(x)$  is equal to integral of  $a$  to  $b$   $w(x) f^2(x)$  to the power of half, where  $w(x)$  is the weight function that we are talking of earlier, is the weight function and which is greater than 0. So we can use this definition of Euclidean norm to obtain the values of the constants that we have just now defined in the error. In this case we would get what is known as the least square approximation; we obtain the least squares approximation, if I use this particular norm and determine the constants  $c_i$  such that this norm is minimized. Now we use another norm which we shall call it as uniform norm, uniform norm. Again if you are given a data, I would define norm of  $x$  is equal to the largest element in magnitude, maximum of  $x_i$ , of  $x_i$  and if you are given a continuous function again, if you are given a continuous function then we define this as, norm of  $f(x)$  is equal to maximum in the interval  $a$  to  $b$  of magnitude of  $f(x)$ . Now we use this, either for the discrete data that is given or if you are given a continuous function, now if I use this particular norm to determine the constants  $c_i$  then what I would get is known as the uniform approximation, we get uniform approximation in this case. Now in our next lecture we shall see how we have actually apply this minimization problem that is the minimization of the norm to get least square of approximation or minimize these norms to get uniform approximation and thereby construct a polynomial or a function in terms of the orthogonal polynomials which gives us the best approximation gives us the best approximation. Okay, thank you.
