#### Numerical Differentiation and Integration (Continued)

In our previous lectures we have derived numerical methods for numerical differentiation; we laid particular emphasis on the possible numerical instability that can arise in differentiation. We have also laid emphasis on using a lower order formula, if first order or second order formula and then using Richardson extrapolation to improve the results, very often very dramatically the results would improve by using the numerical differentiation of lower order and then applying the Richardson extrapolation. Let us now see how do we go about solving the problems of numerical integration, so let us now take up numerical integration.

(Refer Slide Time: 01:44)

What we are looking for is to write a formula for evaluating and integral of the form, integral of  $a$  to  $b$   $w(x) f(x) dx$  where  $w(x)$  is a weight function, a positive quantity which is a weight function. Wherever the weight function is not required we will take the integrand as a single quantity as  $w(x) f(x)$  as a single quantity but whenever we are required a weight function to use a

particular integration formula we shall then use that weight function for the purpose. Now the interval  $a$  to  $b$  may be finite, it can be semi infinite or infinite, so the interval  $[a, b]$  can be finite interval, it can be semi infinite interval so that we have this as  $0$  to infinity or it may be infinite. We shall consider all the three cases and derive numerical methods for obtaining this particular integral. The formulas usually are called the integration formulas or quadrature formulas, so we can come across both the names by called integration formulas or they are also called rules or they are called quadrature rules. Now what we would like to write is, since the integrand contains the unknown function  $f(x)$ ,  $w(x)$  is a weight function which is known, the integral must be a linear combination of  $f(x)$  evaluated at a number of points between  $a$  and  $b$ .

(Refer Slide Time: 03:55)

$$I = \int_a^b w(x) f(x) dx$$
 $w(x) > 0$  : weight function.  
 $[a, b]$  : finite, semi-infinite  $[0, \infty)$   
                   infinite  $(-\infty, \infty)$   
 Integration formulas/rules  
 quadrature rules.  

$$I = \int_a^b w(x) f(x) dx \approx \sum_{k=0}^n \lambda_k f(x_k)$$
 $x_k \in (a, b) : x_0 = a, x_n = b.$

Therefore I must be able to write this integral  $I$  that is equal to integral  $a$  to  $b$   $w(x) f(x) dx$  as a linear combination approximately as  $k$  is equal to  $0$  to  $n$   $\lambda_k f(x_k)$ ,  $\lambda_k$ 's are there parameters and we are evaluating  $f(x)$  at a number of points in the interval  $a$  to  $b$  and these points  $x_k$ 's or lying between in  $(a, b)$ . Of course we shall be using the end points also, wherever it is necessary we shall use the end points, for example I can use  $x_0$  is equal to  $a$  and I can use  $x_n$  the last point as  $b$  also. However we can construct formulas which do not use the values at the end points.

(Refer Slide Time: 04:56)

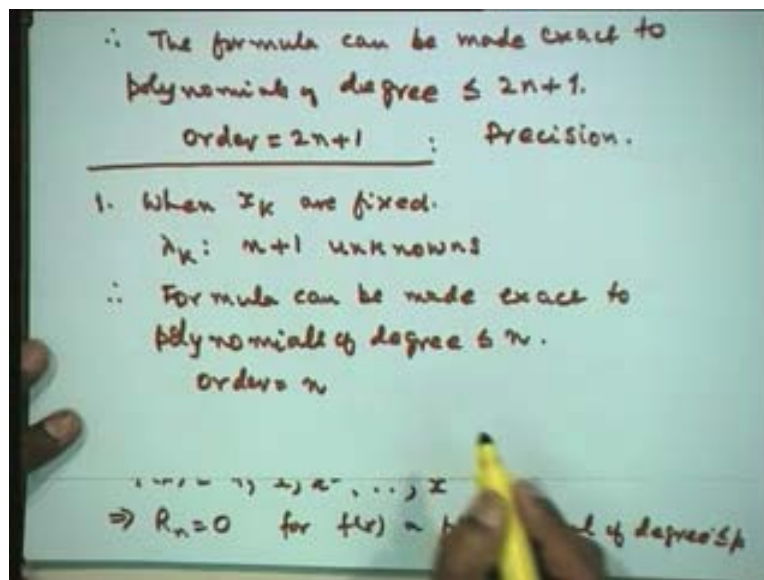

$x_k$ : abscissas :  $n+1$   
 $\lambda_k$ : weights :  $n+1$  }  $2n+2$  unknowns  
 $n+1$  point rule.  
Error:  
$$R_n = \int_a^b w(x) f(x) dx - \sum_{k=0}^n \lambda_k f(x_k)$$
  
Order : order  $p$ :  
If the rule integrates exactly polynomials of degree  $\leq p$ , then order =  $p$   
 $f(x) = 1, x, x^2, \dots, x^p$   
 $\Rightarrow R_n = 0$  for  $f(x)$  = polynomial of degree  $\leq p$

Since we are using, we shall also call the  $x_k$ 's as abscissas of the quadrature rule, we shall call this as abscissas of the quadrature rule and  $\lambda_k$ 's shall be called as weights of the quadrature rule, so these are weights and abscissas of a quadrature rule. Now we can see that we are using in the integration formula a total number of  $n$  plus  $1$  abscissas, since we are using  $n$  plus  $1$  abscissas we shall call this as a  $n$  plus  $1$  point rule, so we shall call this as a  $n$  plus  $1$  point rule. Now as given in this formula these  $x_k$  abscissas there are  $n$  plus  $1$  that are there, there are  $n$  plus  $1$  weights also in this formula. If we take both of them as unknowns that is abscissa also to be determined,  $\lambda_k$ 's also to be determined then there are a total of  $2n$  plus  $2$  unknowns, this will be  $2n$  plus  $2$  unknowns in the general case. Now the error in the integration rule, we shall define it as, we bring the right hand side to the left hand side and write down that as a error in the integration rule, so I can define the error as some  $R_n$  is equal to integral  $a$  to  $b$   $w(x) f(x) dx$  minus summation  $k$  is equal to  $0$  to  $n$   $\lambda_k f(x_k)$ .

Now we need to define the order of a formula before we derive a formula, numerical integration formula, let us define the order of a formula. So let us say the order is  $p$ , let us say we call it as order  $p$ . Now the method will be of order  $p$  if this rule integrates exactly polynomials of degree less than or equal to  $p$ , so it must be able to integrate this exactly so if I use, if  $f(x)$  happens to be a polynomial degree less than or equal to  $p$ , I substitute here, error would become  $0$  or it will exactly be, this will be an exact identity and I will have this is equal to this formula. If the, if the rule integrates exactly polynomials of degree less than or equal to  $p$  then order is equal to  $p$ . Now when we say polynomials of degree less than or equal to  $p$  it would imply that it is sufficient for us to consider  $1, x, x$  square so on  $x$  to the power of  $p$  because obviously if it is integrating these individually a linear combination  $a_0$  plus  $a_1 x$  plus  $a_2 x$  square it will automatically, also it will integrate exactly, so if you want to test whether it is integrating exactly or not we just choose  $f(x)$  is equal to  $1, x, x$  square,  $x$  to the power of  $p$ , substitute in this formula then this would

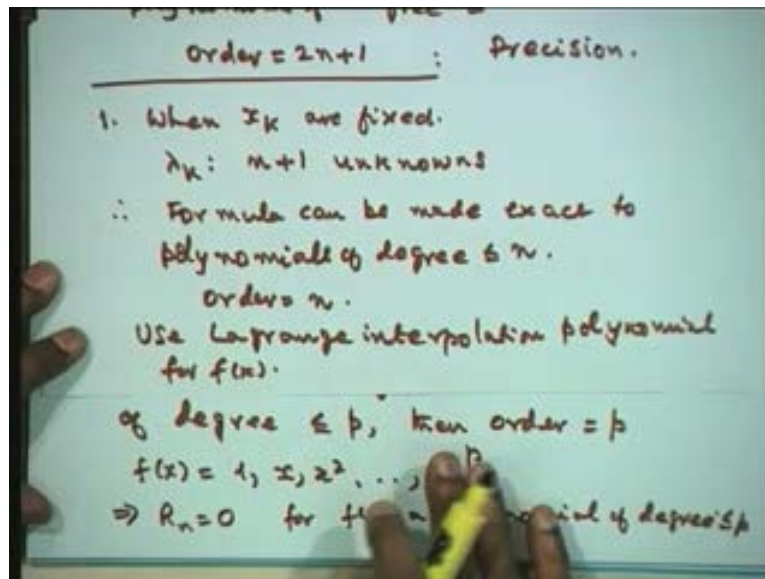

immediately give that error is 0, so it is integrating exactly. So this would also imply that  $R_n$  is equal to 0 for  $f(x)$  a polynomial of degree less than or equal to  $p$ . So the error would be 0 if  $f(x)$  is a polynomial of degree less than or equal to  $p$ . So this is how one can check whether the order is 1, 2 or 3 by just substituting it and then showing that the error is equal to 0 in these particular cases. Now in the general case we said that the formula has got  $2n + 2$  unknowns, hence **we can**, we can consider it as if it is a data given to us at  $2n + 2$  points therefore we can find a formula which will have the order  $2n + 1$ .

(Refer Slide Time: 09:46)

So therefore if you have, since the number of unknowns, number of unknowns in the general case is equal to  $2n + 2$  therefore the formula can be made exact to polynomials of degree less than or equal to  $2n + 1$  that means we are talking the order of the formula can be made as  $2n + 1$ . Sometimes the order is also called precision, so we can also use the alternative name as the precision of the formula. Now if you want to use the result that we know in the interpolation particularly to the Lagrange interpolation or the other interpolations, there the abscissas are all fixed so the data is given to us  $x(k)$ , so  $x(k)$  is fixed therefore if I want to use that formula I need to fix my  $x_k$ 's. So let us consider the case when  $x_k$ 's are fixed, if  $x_k$  are fixed we have only  $\lambda_k$ 's to be determined therefore these are  $n + 1$  unknowns, where therefore only  $n + 1$  unknowns to be determined. Hence we can make the formula exact polynomials degree less than or equal to  $n$ , therefore the formula can be made exact to polynomials of degree less than or equal to  $n$  that means order of the formula can be made is equal to  $n$ . Now when once you say that  $x_k$ 's are fixed then we can immediately say that we can use the Lagrange interpolation formula.

(Refer Slide Time: 12:06)

Therefore use Lagrange interpolation, Lagrange interpolation polynomial for  $f(x)$ .

(Refer Slide Time: 12:32)

$$\int_a^b w(x) f(x) dx = \int_a^b w(x) \left[ \sum_{k=0}^n l_k(x) f(x_k) + \frac{\pi(x)}{(n+1)!} f^{(n+1)}(\xi) \right] dx$$

$a = x_0 < x_1 < x_2 < \dots < x_n = b.$

$$\int_a^b w(x) f(x) dx = \sum_{k=0}^n f(x_k) \int_a^b w(x) l_k(x) dx + \frac{1}{(n+1)!} \int_a^b w(x) \pi(x) f^{(n+1)}(\xi) dx$$

$$= \sum_{k=0}^n \lambda_k f(x_k) + R_n$$

Therefore we write integral a to b  $w(x) f(x) dx$  is equal to integral a to b  $w(x)$  into [summation k is equal to 0 to n  $l_k(x) f(x_k)$  plus  $\pi(x)$  upon  $(n+1)$  factorial  $f^{(n+1)}(\xi) dx$ , where the abscissas

$x_k$ 's are given by  $a = x_0 < x_1 < x_2$  and so on less than  $x_n$  is equal to  $b$ . Now let us simplify the right hand side, we write it as a sum of two integrals, integral of the first one and the integral of the second one, in the first integral we can take the summation outside the integral sign also  $f$  of  $x_k$  is independent of  $x$  therefore we can take  $f(x_k)$  also out of the integral sign therefore we get integral  $a$  to  $b$   $w(x) f(x) dx$  is equal to summation  $k$  is equal to  $0$  to  $n$   $f$  of  $x_k$  into integral  $a$  to  $b$   $w(x) l_k(x) dx$  plus  $1$  upon  $(n+1)$  factorial integral  $a$  to  $b$   $w(x) \pi(x) f^{(n+1)}(x) dx$ . Note that  $\pi$  is dependent on  $x$  therefore I cannot take  $f^{(n+1)}$  outside the integral and write it, it will be part of the integrand, now this integral is difficult for us to evaluate. Now we will set it equal to summation  $k$  is equal to  $0$  to  $n$  some  $\lambda_k f$  of  $x_k$  plus  $R_n$ , where we have denoted this integral by  $\lambda_k$  and this error term as  $R_n$ .

(Refer Slide Time: 15:09)

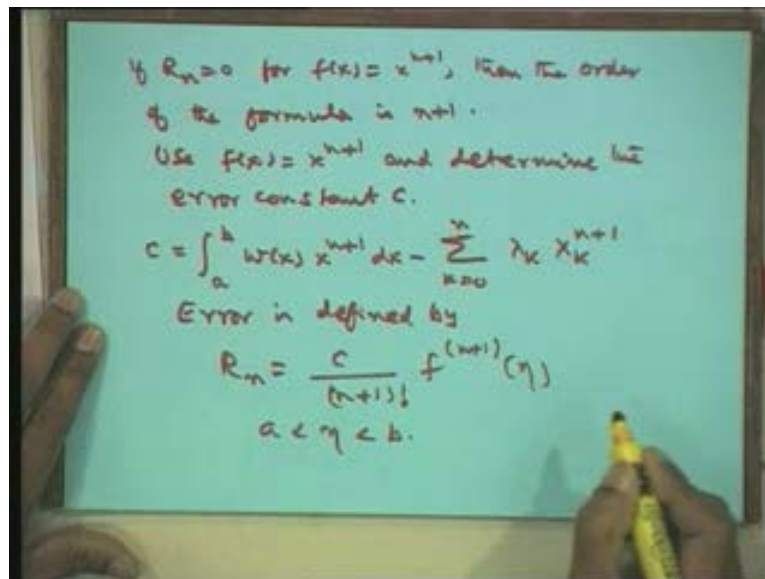

$$\lambda_k = \int_a^b w(x) l_k(x) dx$$

$$R_n = \frac{1}{(n+1)!} \int_a^b \pi(x) w(x) f^{(n+1)}(x) dx$$
Alternate method for finding  $R_n$   
 Formula is of order  $n$   
 $\therefore$  Integrates exactly all polynomials of degree  $\leq n$ .  
 $f(x) = 1, x, x^2, \dots, x^n$   
 $\Rightarrow f(x) = x^{n+1}, R_n \neq 0$

Therefore we can write  $\lambda_k$  is equal to  $\int_a^b w(x) l_k(x) dx$  and the error term  $R_n$  is  $1$  upon  $(n+1)$  factorial, integral  $a$  to  $b$   $\pi(x) w(x) f^{(n+1)}(x) dx$ . As I mentioned earlier it is difficult for us to evaluate this integral unless this part  $\pi(x)$  into  $w(x)$  has got some special properties which may, may not have always have it therefore I would like to write an alternative method for finding  $R_n$ , so let us call this as alternate method for finding  $R_n$ . We know that the formula is of order  $n$  so that is the first step that we shall note, therefore it integrates all polynomials of degree less than or equal to  $n$ , integrates exactly all polynomials of degree less than or equal to  $n$ . That means it integrates exactly  $1, x, x$  square and so on  $x$  to the power of  $n$ . This implies that if  $f(x)$  is equal to  $x$  to the power of  $n+1$  then  $R_n$  is not equal to  $0$ , this error is not going to be equal to  $0$  therefore if  $R_n$  is equal to  $0$  then it is going to integrate exactly polynomials of degree  $n+1$  also. Hence if we use  $x$  to the power of  $n+1$ , now if  $R_n$  is equal to  $0$  for  $f(x)$  is equal to  $x^{n+1}$  then the formula is of order  $n+1$ .

(Refer Slide Time: 17:24)

That means, hence we shall use  $f(x)$  is equal to  $x$  to the power of  $n$  plus 1 and determine the error constant in the error. We shall call the error constant as  $C$ , you can call it by any other name. Therefore  $C$  is defined by integral  $a$  to  $b$   $w(x) x$  to the power of  $n$  plus 1  $dx$  minus summation  $k$  is 0 to  $n$   $\lambda_k x_k^{n+1}$ . In the integration rule  $f(x)$  is replaced by  $x$  to the power of  $n$  plus 1,  $f$  of  $x_k$  is replaced by  $x_k$  to the power of  $n$  plus 1. Then error is defined by,  $R_n$  is  $C$  upon  $(n$  plus 1) factorial  $f$  of  $n$  plus 1 of  $\eta$ , where  $\eta$  lies between  $a$  and  $b$ .

(Refer Slide Time: 19:00)

Let  $w(x) = 1$

$$\lambda_k = \int_a^b l_k(x) dx$$

$$= \int_{x_0}^{x_n} \frac{(x-x_0)(x-x_1)\dots(x-x_{k-1})(x-x_{k+1})\dots(x-x_n)}{(x_k-x_0)(x_k-x_1)\dots(x_k-x_{k-1})(x_k-x_{k+1})\dots(x_k-x_n)} dx$$

Equi spaced abscissas

Let  $\frac{x-x_0}{h} = s$  ;  $x = x_0 + sh$

$$x - x_i = x - (x_0 + ih) = x - x_0 - ih$$

$$= sh - ih = (s-i)h$$

So let us take, let  $w(x)$  is equal to 1 that is weight function is equal to 1. Then our  $\lambda_k$ 's would be simply integral  $a$  to  $b$   $l_k(x) dx$ , so  $w(x)$  is equal to 1 it is simply the integral of the Lagrange fundamental polynomials that is  $l_k(x)$  and let us open it up. Therefore this is equal to integral of,  $a$  is equal to  $x_0$ ,  $b$  is equal to  $x_n$   $(x \text{ minus } x_0) (x \text{ minus } x_1) (x \text{ minus } x_{k-1}) (x \text{ minus } x_{k+1}) (x \text{ minus } x_n)$  divide by  $(x_k \text{ minus } x_0) (x_k \text{ minus } x_1) (x_k \text{ minus } x_{k-1}) (x_k \text{ minus } x_{k+1}) (x_k \text{ minus } x_n) dx$ . I have written the Lagrange fundamental polynomial with respect to the abscissa  $x_k$  because left hand side I have written  $\lambda_k$ , I will write corresponding to  $\lambda_k$  **if the**, in the formula it is  $\lambda_k f(x_k)$  so I will be writing  $\lambda_k$  with respect to the abscissa  $x_k$  therefore I will be missing the term in the numerator  $(x \text{ minus } x_k)$  and this is the Lagrange fundamental polynomial.

Now I will assume that we are taking the equi space, let us take the equi space, equi spaced abscissas, equi space and let us define  $(x \text{ minus } x_0)$  by  $h$  is equal to some  $s$ , which is same as  $x$  is equal to  $x_0$  plus  $sh$ . Now with respect to this particular substitution I would like to derive what is a numerator and denominator. For example  $x \text{ minus } x_i$  would be equal to  $x \text{ minus } (x_0 \text{ plus } ih)$ ,  $x_i$  is equal to  $(x_0 \text{ plus } ih)$ , which is same as  $x \text{ minus } x_0 \text{ minus } ih$  but  $x \text{ minus } x_0$  is  $s$  into  $h$  that is equal to  $s$  into  $h \text{ minus } i$  into  $h$  that is  $(s \text{ minus } i) \text{ into } h$ . So I can set  $i$  is equal to 0, 1, 2, 3 so on and then I can obtain the expression for each one of these terms that we have over here and similarly if I take the denominator, denominator is  $x_k \text{ minus } \text{some } x_i$ ,  $x_k$  is fixed,  $x_i$  is varying. Therefore this I can write as  $x_0 \text{ plus } kh$  and  $x_i$  is equal to  $(x_0 \text{ plus } ih)$  therefore this is  $(k \text{ minus } i) \text{ into } h$ . Therefore we are able to get the expression for each one of these factors that we have here, so let us now write down what is the denominator.

(Refer Slide Time: 22:55)

Handwritten derivation on a whiteboard:

$$\begin{aligned} \text{Denominator} &= (kh)[(k-1)h] \dots [h] [-h] \dots [(n-k)h] \\ &= h^n (-1)^{n-k} k! (n-k)! \\ \text{Numerator} &= (sh)[(s-1)h] \dots [(s-k+1)h] [(s-k)h] \dots [(s-n)h] \\ &= h^n s(s-1) \dots (s-k+1)(s-k) \dots (s-n) \\ \lambda_k &= \frac{s^n (-1)^{n-k}}{k! (n-k)!} \end{aligned}$$

A bracket on the right side of the numerator indicates the product from  $s=0$  to  $s=n$ .

Now denominator, if I take this first term is  $(x_k \text{ minus } x_0)$  so  $i$  is equal to 0 so first term is  $k h$ , so I will have here  $(k h)$ . The next term is  $(x_k \text{ minus } x_1)$   $i$  is 1 that is  $(k \text{ minus } 1)$  into  $h$ ,  $[(k \text{ minus } 1) \text{ into } h]$  and so on, I have got here  $(x_k \text{ minus } x_{k-1})$  therefore  $k \text{ minus } k \text{ minus } 1$  therefore I will have plus 1 into  $h$ , so I will have  $h$  here. Now the next term is  $(x_k \text{ minus } x_{k+1})$  therefore I will have here minus  $k \text{ minus } 1$  so I will have here  $[\text{minus } h]$  and so on, the last term is  $[(n \text{ minus } k) \text{ into } h]$  this is your  $(n \text{ minus } k)$  with a negative sign, I have written  $(n \text{ minus } k)$ , this is your  $(k \text{ minus } 1) \text{ into } h$  so this is **minus  $n \text{ minus } 1$  into  $k$** .

Now let us simplify this, there number of terms here are  $n$ , number of terms are  $n$  therefore each one is giving us a  $h$  for us, so it is giving  $h$  to the power of  $n$ . With negative sign there are  $n \text{ minus } k$  terms, so I will have minus 1 to the power of  $n \text{ minus } k$ . And the, if you look at the first one this is 1 into 2 into 3 into  $k$  so this will contribute factorial  $k$ . This is 1 into 2 into 3  $(n \text{ minus } k)$  so this will give you  $(n \text{ minus } k)$  factorial. This will be the denominator, the simplified form of the denominator. Now let us write down the numerator. Now here we have  $(x \text{ minus } x_0)$  therefore I have to substitute  $i$  is equal to 0 in this, therefore this is  $s$  into  $h$  therefore I will have  $s$  into  $h$  as the first term. Then I substitute  $i$  is equal to 1 so I will have  $[(s \text{ minus } 1) \text{ into } h]$  and I have to go up to  $(x \text{ minus } x_{k-1})$  so will have here  $[(x \text{ minus } k \text{ plus } 1) \text{ into } h]$ . Then we have  $(x \text{ minus } x_{k+1})$  therefore I will have  $[(s \text{ minus } k \text{ minus } 1) \text{ into } h]$  and so on. And the last term is  $(x \text{ minus } x_n)$  so I put  $i$  is equal to  $n$ , so  $s \text{ minus } 1$  into  $h$  so I will have here is,  $[(s \text{ minus } n) \text{ into } h]$ . Number of terms are  $n$  therefore I will have here  $h$  to the power of  $n$  again and the remaining is  $s$  into  $(s \text{ minus } 1)$ ,  $(s \text{ minus } k \text{ plus } 1)$ ,  $(s \text{ minus } k \text{ minus } 1)$ ,  $(s \text{ minus } n)$ . Now I can substitute the denominator and the numerator in  $\lambda_k$ , so if I do that let us write down  $\lambda_k$ . Now the, when I substitute  $h$  to the power of  $n$  cancels with  $h$  power of  $n$ , so we can drop of  $h$  to the power of  $n$ .

(Refer Slide Time: 26:57)

Let  $w(x) = 1$

$$\lambda_k = \int_a^b l_k(x) dx$$

$$= \int_{x_0}^{x_n} \frac{(x-x_0)(x-x_1)\dots(x-x_{k-1})(x-x_{k+1})\dots(x-x_n)}{(x_k-x_0)(x_k-x_1)\dots(x_k-x_{k-1})(x_k-x_{k+1})\dots(x_k-x_n)} dx$$

Equidistant abscissas

Let  $\frac{x-x_0}{h} = s$  ;  $x = x_0 + sh$   $dx = h ds$

$$x - x_i = x - (x_0 + ih) = x - x_0 - ih$$

$$= sh - ih = (s-i)h$$

$$x_k - x_i = x_0 + kh - (x_0 + ih) = (k-i)h$$

Furthermore we have  $dx$  here and  $dx$  is equal to  $s$  times  $dh$ , will have here, is equal to  $h$  times  $ds$ . Therefore  $dx$  is also contributing  $1/h$  term, therefore I will have outside  $h$  here, these  $h$  to the power of  $n$  cancelled, this is minus 1 to the power of  $(n - k)$  I will retain it as it is, denominator is factorial  $k$   $(n - k)$  factorial, so this is the term in the denominator, this is the negative sign whether you write numerator or denominator it is same, so I have written this and integral of the lower limit is  $x_0$ . When I substitute  $x_0$  here,  $s$  will be 0, when I put  $x$  is equal to  $x_n$  this is  $nh$  by  $h$  that is  $n$  therefore  $s$  will be  $n$ , therefore the limits of integration are, for  $s$  is equal to 0 to  $n$ , the limits for  $s$  are 0 to  $n$ .

(Refer Slide Time: 28:04)

$$\begin{aligned}
 & (kh)(k-1)h \dots [h] [-h] \dots \frac{(-1)^{n-k} h^n}{2} \\
 & = h^n (-1)^{n-k} k! (n-k)! \\
 \text{Numerator} & = \\
 & = (sh) [(s-1)h] \dots [(s-k+1)h] [(s-k-1)h] \\
 & \quad \dots [(s-n)h] \\
 & = h^n s(s-1) \dots (s-k+1)(s-k-1) \dots (s-n) \\
 \lambda_k & = \frac{h^n (-1)^{n-k}}{k! (n-k)!} \int_0^n s(s-1) \dots (s-k+1)(s-k-1) \dots (s-n) ds
 \end{aligned}$$

And the integral is given by simply this quantity that is  $s$  into  $(s \text{ minus } 1)$  so on  $(s \text{ minus } k \text{ plus } 1)$ ,  $(s \text{ minus } k \text{ minus } 1)$  so on  $(s \text{ minus } 1)$   $ds$ . Now we can also write down from here what will be the error term, the error term that we had written is this, so I can write down the error term from this using this, let us write error that is equal to  $R_n$ .

(Refer Slide Time: 28:40)

$$\begin{aligned}
 \text{Error} \\
 R_n & = \frac{h^{n+2}}{(n+1)!} \int_0^n s(s-1) \dots (s-n) f^{(n+1)}\left(\frac{s}{3}\right) ds \\
 \text{Newton-Cotes Formulas} \\
 n=1 & \quad \text{Two point formula} \quad (x_0, f(x_0)) \\
 & \quad \quad \quad \quad \quad \quad \quad (x_1, f(x_1)) \\
 h & = x_1 - x_0 = b - a
 \end{aligned}$$

Now the numerator  $w(x)$  is 1 we have taken,  $\pi(x)$  contains all the products, all the products means it will now contain the missing factor also that we have missed here  $(s - k)$  so that missing factor will come here and hence it will be  $h$  to the power of  $n + 1$  and there is a  $h$  being contributed by  $dx$ , therefore we will have here  $h$  to the power of  $n + 2$ ,  $h$  to the power of  $n + 1$  contributed by this and  $dx$  is equal to  $h$  times  $ds$ . Denominator is the same that is your  $n + 1$  so we will have  $(n + 1)$  factorial, integral of 0 to  $n$  and the  $s$  into  $(s - 1)$ , all the terms are here so simply  $(s - 1)^{(n+1)}$  of  $zhi ds$ . This is the error term for the most general case and these  $\lambda_k$ 's are the weights in the integration formula and this entire set of formulas are called Newton-cotes formulas; they are called Newton-cotes formulas. If I take particular values of number of points  $n$  then I have various order formulas coming, let us first of all take a case  $n$  is equal to 1 which is a 2 point formula, this will be a 2 point formula. We are taking  $n + 1$  as the total number of points so if I take  $n$  is equal to 1, we are taking 2 point formula that is your  $x_0$  we are taking,  $f(x_0)$  we are taking and  $(x_1, f(x_1))$ , these are the 2 points that we are taking. Therefore  $h$  will be simply equal to  $x_1$  minus  $x_0$  that is equal to simply  $b$  minus  $a$ . We are taking the entire interval  $a$  to  $b$  as only considering 2 points therefore it will be the upper limit and the lower limit therefore the distance between them will be your step length  $b$  minus  $a$ .

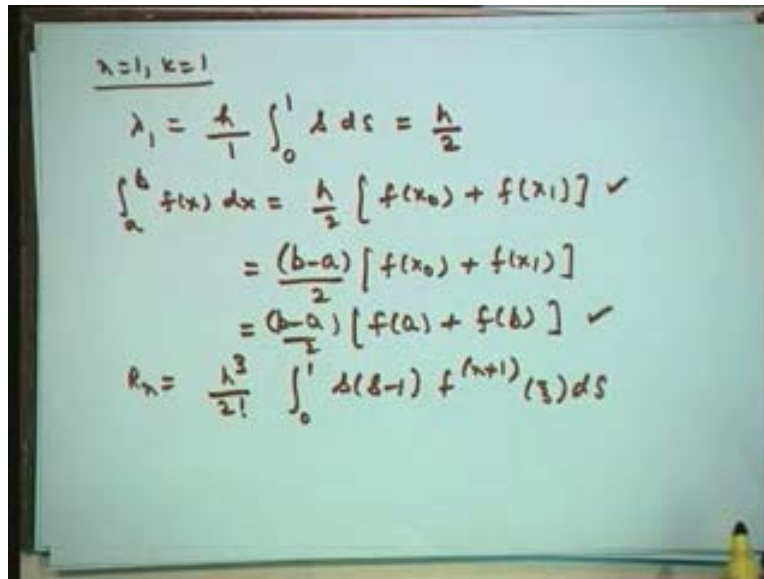

(Refer Slide Time: 31:12)

$$\begin{aligned}
 &= h^n s(s-1) \dots (s-k+1)(s-k-1) \dots (s-n) \\
 \lambda_k &= \frac{h (-1)^{n-k}}{k! (n-k)!} \int_0^n s(s-1) \dots (s-k+1)(s-k-1) \dots (s-n) ds \\
 h &= x_1 - x_0 = b - a \\
 \int_a^b f(x) dx &= \lambda_0 f(x_0) + \lambda_1 f(x_1) \\
 \underline{n=1, k=0} \quad \lambda_0 &= -\frac{h}{1} \int_0^1 (s-1) ds \\
 &= -h \left[ \frac{s^2}{2} - s \right]_0^1 = \frac{h}{2}
 \end{aligned}$$

The formula will be integral of  $a$  to  $b$   $f(x)dx$ ,  $w$  is equal to 1 so  $f(x)dx$  is  $\lambda_0 f$  of  $x_0$  plus  $\lambda_1 f$  of  $x_1$ , this is our formula of which  $x_0$  and  $x_1$  are fixed as  $a$  and  $b$ . Now  $\lambda_0$  I can obtain from here, let us substitute  $k$  is equal to 0 in this to get our value, so I have to put  $n$  is equal to 1,  $k$  is equal to 0, I have to put here and  $k$  is equal to 0 and  $n$  is equal to 1. Therefore we will get  $\lambda_0$  is equal to,  $n$  is 1,  $k$  is 0 so I will have a minus sign, minus  $h$ , this is factorial 0, factorial 1 so I will have denominator simply as 1. Integral of 0 to 1 that only  $n$  is equal to 1, 0 to 1 and the numerator should not contain  $x$  minus  $s$   $k$  term that is your  $x$  minus  $x_0$  term that means

I should not have  $s$  in the integrant, so I will simply have  $s$  minus 1  $ds$ . since we have taken only  $n$  is equal to 1 will have to consider only 2 terms of this, so of this  $\lambda_{k=0}$   $s$  will be missing, for  $\lambda_{k=1}$   $s$  minus 1 will be missing, so  $s$  missing so I will have simply this. Now I can integrate this and write this minus  $h$   $s$  square by 2 that is half minus  $s$  that is 1, so that is equal to  $h$  upon 2. Now we have obtained already  $\lambda_{k=0}$  so let us obtain  $\lambda_{k=1}$ .

(Refer Slide Time: 33:02)

The image shows a whiteboard with handwritten mathematical derivations. At the top, it says  $n=1, k=1$ . Below that, the first equation is  $\lambda_1 = \frac{h}{1} \int_0^1 s \, ds = \frac{h}{2}$ . The second equation is  $\int_a^b f(x) \, dx = \frac{h}{2} [f(x_0) + f(x_1)] \checkmark$ . This is followed by two equivalent forms:  $= \frac{(b-a)}{2} [f(x_0) + f(x_1)]$  and  $= \frac{(b-a)}{2} [f(a) + f(b)] \checkmark$ . The final equation is  $R_n = \frac{h^3}{2!} \int_0^1 s(s-1) f^{(n+1)}(\xi) \, ds$ .

So now I have to take  $n$  is equal to 1,  $k$  is equal to 1, I have to take  $n$  is equal to 1,  $k$  is equal to 1. So let us put in this  $n$  is equal to 1,  $k$  is equal to 1, therefore I will have  $\lambda_{k=1}$ , now  $n$  is 1,  $k$  is 1 so it will be positive sign and this is 1 factorial, this is 0 factorial so again I will have 1. 0 to 1 now  $s$  minus 1 will be missing so I will simply have  $s \, ds$ . Therefore this will give you  $h$  square by 2,  $s$  square by 2 therefore that's equal to  $n$  by 2. Therefore we have now derived the formula as integral  $a$  to  $b$   $f(x)dx$  is equal to  $h$  by 2 [ $f$  of  $x_0$  plus  $f$  of  $x_1$ ]. If you want we can put it in terms of the upper and lower limit also,  $h$  is equal to  $b$  minus  $a$  so I can alternatively write this as  $(b$  minus  $a)$  by 2 [ $f(x_0)$  plus  $f$  of  $x_1$ ] and again  $(b$  minus  $a)$  by 2 [ $f$  of  $a$  plus  $f$  of  $b$ ]. So I can use this particular form or I can use this particular form for computation purposes. Now let us write down the error term, the error term is given by this, now  $n$  is equal to 1 therefore our error  $R_n$  is  $h$  cubed by factorial 2, I am putting  $n$  is equal to 1 here, 0 to 1  $s$  into  $(s$  minus 1)  $f^{(n+1)}(\xi) \, ds$ .

(Refer Slide Time: 35:07)

$$\lambda_1 = \frac{h}{1} \int_0^1 \Delta ds = \frac{h}{2}$$

$$\int_a^b f(x) dx = \frac{h}{2} [f(x_0) + f(x_1)] \checkmark$$

$$= \frac{(b-a)}{2} [f(x_0) + f(x_1)]$$

$$= \frac{(b-a)}{2} [f(a) + f(b)] \checkmark$$

$$R_n = \frac{h^3}{2!} \int_0^1 \underbrace{\Delta(s-1)}_{\text{Same sign - : in } (0,1)} f^{(n+1)}(\xi) ds$$

USE M.V.T of integral calculus

Now it is possible sometimes for us to use the mean value theorem of integral calculus to evaluate this as we have done earlier also. You can see that this product, this function  $s$  has got negative sign between 0 and 1 so it has the same sign, it has the same sign, minus sign in  $(0, 1)$ . Therefore I can apply the mean value theorem where we have 0 to 1  $\sum f(x) g(x) dx$  is there,  $f(x)$  does not change its sign then  $g(x)$  can be taken out of the integral and evaluate it at any point in between 0 and 1. So apply the mean value theorem, use mean value theorem of integral calculus.

(Refer Slide Time: 36:04)

Handwritten derivation on a whiteboard:

$$R_n = \frac{h^3}{2!} f''(\eta) \int_0^1 (s^2 - s) ds, \quad a < \eta < b$$

$$= \frac{h^3}{2} f''(\eta) \left[ \frac{s^3}{3} - \frac{s^2}{2} \right]_0^1 = -\frac{h^3}{12} f''(\eta)$$

$$= -\frac{(b-a)^3}{12} f''(\eta) \checkmark$$

Integrates exactly polynomials of degree  $\leq 1$ .

order =  $n = 1$

Trapezoidal / Trapezium rule.

$$\int_a^b f(x) dx$$

If I use this mean value theorem of integral calculus I can now take out this  $f^{(n+1)}$  out and write this as  $h^3$  by factorial 2,  $n$  is equal to 1  $f$  double dashed of some  $\eta$ , some other point some point in this one into integral 0 to 1, let us multiply it out  $s^2$  minus  $s$   $ds$ , where  $\eta$  is lying between  $a$  and  $b$ ,  $\eta$  is lying between  $a$  and  $b$ . Now let us evaluate this, this is equal to  $h^3$  cubed by 2  $f$  double dash of  $\eta$ , this is  $x$  cubed by 3 that is  $[1 \text{ by } 3 \text{ minus } 1 \text{ by } 2]$ . This gives you minus 1 by 6 so minus  $h^3$  cubed by 12  $f$  double dash  $\eta$ . If I want in terms of  $b$  minus  $a$ , I can also write in terms of  $(b \text{ minus } a)$  whole cubed by 12  $f$  double dash of  $\eta$ . Now  $n$  is equal to 1 therefore as we are shown earlier this integral formula integrates exactly polynomials of degree less than or equal to 1, therefore this integrates polynomials of degree less than or equal to 1 that is all linear polynomials it will integrate exactly. Therefore integrates exactly polynomials of degree less than or equal to 1 that is because order is going to be  $n$  is equal to 1.

Indeed, of course we could have observed or derived this particular thing by looking at this error term. The error term consists of  $f$  double dash of  $\eta$ , now if  $f$  is a linear polynomial it is second derivative is 0, therefore  $R_n$  is always going to be 0 whenever, whenever our  $f(x)$  is a linear polynomial. Therefore the conclusion that we have given here could be obtained by if you are able to derive the error formula, I can obtain the same observations from the error formula also. This formula is called the trapezoidal rule or trapezium rule, this is called the trapezium rule, trapezoidal or we can call it as trapezium rule.

(Refer Slide Time: 38:49)

$$\begin{aligned} &= \frac{h^3}{2} f''(\eta) \left[ \frac{1}{3} - \frac{1}{2} \right] = -\frac{h^3}{12} f''(\eta) \\ &= -\frac{(b-a)^3}{12} f''(\eta) \checkmark \end{aligned}$$

Integrates exactly polynomials of degree  $\leq 1$ .  
order  $n = 1$   
Trapezoidal / Trapezium rule.  
 $\int_a^b f(x) dx$

If you are looking at integral  $a$  to  $b$   $f(x) dx$ , why it is called a trapezium I am just trying to explain, if you are taking this is nothing but area under the curve from  $a$  to  $b$   $f(x)$  so if I draw the graph of this, let us write a nice graph like this, let us take this as  $a$ , let us take this as  $b$ , then this is the graph of  $y$  is equal to  $f(x)$ , this gives you area under the curve between the abscissa  $x$  is equal to  $a$   $x$  is equal to  $b$  and bounded by  $y$  is equal to  $f(x)$  above the  $x$  axis. Here what we are doing here is, we have written the formula as simply  $b$  minus  $a$  by  $2$  into  $f$  of  $a$  plus  $f$  of  $b$  that means what we have really done here is, we have now taken this as the approximate area, we have taken this as the approximate area by using this particular formula. This is nothing but the area of trapezium, now if you look at this trapezium this is nothing but the area of the trapezium, therefore it is called the trapezoidal rule or the trapezium rule. Now but the order of the formula is only one therefore it is very useful at the same time we would like to have better formulas.

(Refer Slide Time: 40:14)

$n=2$  Three point formula  
 $x_0, x_1, x_2 : a, \frac{a+b}{2}, b$   
 $\lambda_0 = \frac{h}{3}, \lambda_1 = \frac{4h}{3}, \lambda_2 = \frac{h}{3} :$   
 $h = x_1 - x_0 = x_2 - x_1 = \frac{b-a}{2}$   
 $\int_a^b f(x) dx = \frac{h}{3} [f(x_0) + 4f(x_1) + f(x_2)]$   
 $= \frac{(b-a)}{6} [f(a) + 4f(\frac{a+b}{2}) + f(b)]$   
 Integrate pol of degree  $\leq 2$

So let us go for  $n$  is equal to 2 that is your 3 point formula that means we are using the 3 abscissas  $x_0, x_1, x_2$ , they are equi distant therefore we are taking  $a, a$  plus  $b$  by 2 and  $b$ , these are 3 equi distant formulas therefore we have  $a, a$  plus  $b$  by 2 and  $b$ . Now I will have to substitute in this expression that we have derived earlier for  $\lambda_k$  for finding  $\lambda_0$  I will have to substitute  $n$  is equal to 2,  $k$  is equal 0, integrate this I will have, then I will have 3 terms here  $s$  into  $(s \text{ minus } 1)(s \text{ minus } 2)$  one of them will be dropped for finding  $\lambda_0$  that is  $s$  will be dropped, where I find  $s = 1$ ,  $\lambda_1$ , I will drop  $(s \text{ minus } 1)$ , when I find  $\lambda_2$  I drop  $(s \text{ minus } 2)$ . So it is simply integration of this between the limits 0 to 2; I have to integrate between 0 to 2. Now I will give the values for the  $\lambda$ s that is very simple straight forward to be can be obtained that is  $h$  upon 3,  $\lambda_1$  is equal to  $4h$  by 3 and  $\lambda_2$  is equal to  $h$  by 3.  $h$  of course is the distance between  $x_1$  and  $x_0$  and this, therefore your  $h$  is equal to  $x_1$  minus  $x_0$  or same as  $x_2$  minus  $x_1$  therefore this will be  $b$  minus  $a$  by 2. This is the 3 point so it will be 2 intervals because the 2 intervals we are taking, the 2 intervals are  $x_0, x_1, x_1, x_2$ , therefore the step length that we have will be, having will  $b$  minus  $a$  by 2, so that it is divided into 3 equi distant points.

Therefore the formula would be  $\int_a^b f(x) dx$  is equal to  $h$  by 3 [ $f$  of  $x_0$  4 times  $f$  of  $x_1$  plus  $f$  of  $x_2$ ]. If I write in terms of the  $n$  points, upper and lower limits I can write down  $b$  minus  $a$ , this is 2 therefore I have a 6 here, [ $f$  of  $a$  4 times  $f$  of  $(a \text{ plus } b \text{ by } 2)$  plus  $f$  of  $b$ ]. Now let us write down the error also from here, error formula can immediately be written down but the error formula as given is difficult for me so what I would do is I will write the alternative form of the error that is given to us. We have written the error constant, we have defined the error constant, I would like to use this to derive the error formula for this formula. Now  $n$  is equal to 2 therefore it should integrate polynomials of degree less than or equal to 2 so let us first say integrates

polynomials of degree less than or equal to 2. Therefore our error term should come from the next power of  $x$  that is  $x$  cubed, this is  $n$  is equal to 2 therefore I must use  $x$  to the power of  $n$  plus 1 that is 3 and that should give me the error constant therefore let us write down the error constant.

(Refer Slide Time: 43:52)

$$\begin{aligned}
 c &= \int_a^b x^3 dx - [\lambda_0 f(x_0) + \lambda_1 f(x_1) + \lambda_2 f(x_2)] \\
 &= \frac{1}{4} (b^4 - a^4) - \frac{(b-a)}{6} \left[ f(a) + 4f\left(\frac{a+b}{2}\right) + f(b) \right] \\
 &= \frac{1}{4} (b^4 - a^4) - \frac{(b-a)}{6} \left[ a^3 + \frac{4}{8} (a+b)^3 + b^3 \right] \\
 &= 0 \\
 \therefore \text{Integrates pol. of degree } \leq 3 \text{ exactly.} \\
 \text{Order} &= 3
 \end{aligned}$$

The error constant  $c$  would be equal to integral of  $a$  to  $b$ , integral of  $a$  to  $b$   $x$  cubed  $dx$  minus  $\lambda_0 f(x_0)$ , we will write down this expression but just write down the original formula. Now let us put the value of this, this is equal to integral  $a$  to  $b$ , let us integrate this  $x^4$  by 4 so I will have 1 by 4 ( $b$  to the power of 4 minus  $a$  to the power of 4) minus this is  $b$  minus  $a$  by 6, I am writing from here, I am writing from this formula. This is your  $f$  of  $a$ , I will substitute for  $x$  in a moment but let us just write down the formula, this is 4 times  $f$  of  $(a$  plus  $b$  by 2) plus  $f$  of  $b$ . So let us put the value of  $f$ ,  $f$  is  $x$  cubed therefore this is 1 upon 4 ( $b$  to the power of 4 minus  $a$  to the power of 4) ( $b$  minus  $a$ ) by 6,  $f$  is  $x$  cubed therefore this is  $a$  cubed plus 4 upon 8 ( $a$  plus  $b$ ) whole cubed plus  $b$  cubed.

Now I will leave this as a simple exercise for you to just open it up and show that it turns out to be 0. Just multiply it out everything cancels and we will have only  $b^4$  minus  $a^4$  here and we will get this is equal to 0. Therefore the error constant has turned out to be 0, before we had written this we said it integrates polynomials of degree less than or equal to 2 but now error constant has become 0, so it is integrating  $x$  cubed also exactly, therefore this formula is integrating polynomials of degree less than or equal to 3 exactly. Therefore we conclude from here immediately integrates polynomials of degree less than or equal to 3 exactly, it is not 2 but 3 therefore the order of this formula is now 3.

(Refer Slide Time: 46:39)

$$\begin{aligned}
 c &= \int_a^b x^4 dx - \frac{(b-a)}{6} \left[ a^4 + \frac{4}{16}(a+b)^4 + b^4 \right] \\
 &= -\frac{(b-a)^5}{120} \\
 R_3 &= \frac{c}{4!} f^{(4)}(\eta) = -\frac{(b-a)^5}{24(120)} f^{(4)}(\eta) \checkmark \\
 &= -\frac{32 h^5}{24(120)} f^{(4)}(\eta) = -\left(\frac{h^5}{90}\right) f^{(4)}(\eta) \\
 &\text{Simpson rule} \quad (1/3 \text{ rule})
 \end{aligned}$$

Now I want the constant c therefore I must go to the next term that is I have to go to a to b x to the power of 4 dx that is a next value of x, that is x to the power of 4 dx minus (b minus a) by 6 f of a that is a to the power of 4 upon 16 (a plus b) to the power of 4 plus b to the power of 4, f of a f of a, a plus b by 2 and f of b. Now I can integrate this, this will give you minus 1 upon 5 x to the power of 5 by 5 that is b 5 minus a 5 and this. Now I will leave this also an exercise for you, it comes out to be very simple expression as (b minus a) to the power of 5 by 120. This combines with this and they would all become a perfect factor and it would become (b minus a) to the power of 5 by 120. Therefore our error is not  $R_2$  but  $R_3$ , n is now instead of 2 it has become 3, so  $R_3$  is equal to c upon, if you had written the previous one it will be factorial 3, now c was 0 so I will have factorial 4 f fourth derivative eta. Now this also would now tell us that is the fourth derivative occurring for 5 f therefore integrates exactly all polynomials of degree less than or equal to 3. Therefore we are proving from here also that it is a order 3.

Now I substitute this therefore I will have b minus a by 5 24 into 120  $f^{(4)}$  eta. Now this form I can use alternatively, I would like to use the form of the step length h, the step length h for this was, h was b minus a by 2 therefore I can use b minus a is 2 h, therefore b minus a to the power of 5 will be 2 to the power of 5 32 h to the power of 5 by 24 into 120  $f_4$  eta. This is 28, 80 and 32 cancels off, it becomes 90 so I will have here  $h^5$  by 90,  $f^{(4)}$  of eta. Now this clause of formulas is called the Simpson's integration formulas, these are the Simpson rules. Some books call it as one third rule but whenever we talk of Simpson's rule we always mean this particular rule and this is a formula which has got precision or order 3 and the error term is quite small that is h to the power of 5 by 90 fourth derivative of this. When  $f(x)$  is a continuous function that is given to us

$f^{iv}$  is bounded. Therefore the error is now really governed by this particular factor that we have over here and we can see by improving by one point the order has jumped also and also it has become very very accurate it is going to be. Okay would stop with this.
