Linear Algebra Part – 3

Welcome viewers, this is my third lecture on Linear Algebra. In earlier 2 lectures, we have discussed vector spaces and subspaces. This lecture is about linear independence and dependence.

(Refer Slide Time: 00:46)

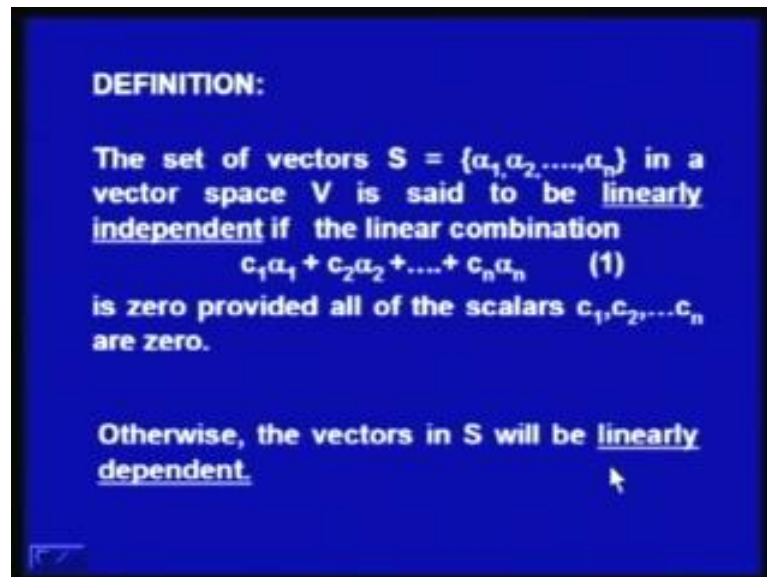

We have all ready define spanning set of lecture space V . As a set W , consisting of n vectors $\alpha_1, \alpha_2, \dots, \alpha_n$, such that every vector in V can be expressed as a linear combination of vectors of W . For example, W_1 consisting of 3 vectors $(1, 0, 0)$, $(0, 1, 0)$ and $(1, 1, 1)$, it can spans \mathbb{R}^3 , the vector space. You can check that, all the vectors in \mathbb{R}^3 can be expressed as a linear combination of these vectors $(1, 0, 0)$, $(0, 1, 0)$ and $(1, 1, 1)$.

We can have another exercise in which another subset W_2 , consisting of $(1, 1, 0)$, $(0, 1, 0)$, $(1, 1, 0)$ and $(1, 1, 1)$, also spans \mathbb{R}^3 . Viewers can check that, they actually represent any vector, in fact, any linear combination of this vector can be a vector space in V . Not only this, any vector V , any vector in V can be exposed as a linear combination of these vectors. So, W_1 and W_2 , both span \mathbb{R}^3 .

This is not all you can have another subset W_3 , consisting of different set of vectors $(1, 0, 0)$, $(0, 1, 0)$, $(0, 0, 1)$, $(1, 1, 1)$ and $(1, 1, 0)$ spans R^3 . This can also be checked, in fact, one may notice that there are number of subsets, which can span the vector space V . So, they may be sets w_1, w_2, w_m spanning vector space V .

(Refer Slide Time: 02:59)

Now, the question is, can we find a minimal spanning set? For this, we will be giving some definitions first and then some results. So, the first definition says, that the set of vectors S consisting of $\alpha_1, \alpha_2, \dots, \alpha_n$. In a linear vectors space V is linearly independent. If the linear combination of these vectors, that is $c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_n \alpha_n$ is 0. Provided all the scalar c_1, c_2, \dots, c_n is 0. So, if this is possible, then the vectors are linearly independent.

(Refer Slide Time: 03:49)

The set S has linearly dependent vectors if there exist some nonzero c_i, S for which the linear combination (1) is zero

The vectors are linearly independent or dependent, we need to find the solution of

$$c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_n \alpha_n = 0$$

Otherwise, the vectors in S will be linearly dependent by this I mean to say, that the set S has linearly dependent vectors, if there exist some nonzero c_i, S , for which the linear combination (1) is zero. The vectors are linearly independent or dependent. We need to find the solution of this equation. That is $c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_n \alpha_n = 0$.

(Refer Slide Time: 04:17)

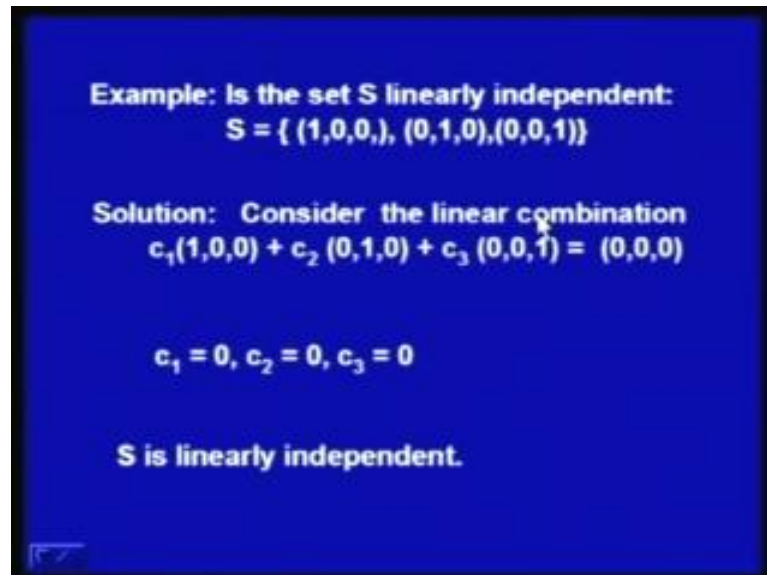

If only the trivial solution
 $c_1 = c_2 = c_3 = \dots = c_n = 0$
is possible, then the vectors are linearly independent.

If one or more of the c 's are nonzero then the set S is linearly dependent.

So, if you find a trivial solution of equation in which c_1, c_2, c_3, c_n all are 0. Then, the vectors are linearly independent. So, if such a solution is possible, then the vectors are

linearly independent. However, if one or more of the c 's are nonzero. Then, the set S is linearly dependent.

(Refer Slide Time: 04:43)

Example: Is the set S linearly independent:
 $S = \{ (1,0,0), (0,1,0), (0,0,1) \}$

Solution: Consider the linear combination
 $c_1(1,0,0) + c_2(0,1,0) + c_3(0,0,1) = (0,0,0)$

$c_1 = 0, c_2 = 0, c_3 = 0$

S is linearly independent.

We can take some examples to illustrate this. So, let us say we have a set S consisting of $(1, 0, 0)$, $(0, 1, 0)$, $(0, 0, 1)$. We have to see, whether this set is linearly independent or dependent. Now, for this, we consider the linear combination $c_1(1, 0, 0)$ plus $c_2(0, 1, 0)$ plus $c_3(0, 0, 1)$ and this right hand side is equal to 0. So, let us consider this linear combination and set it to 0. If we can find a solution of this, which is trivial solution, then we say the vectors are linearly independent. Otherwise, the vectors are linearly dependent.

Now, if one can notice that, these will give rise to three equations. If you compare component wise, so only this component c_1 into 1, this is not contributing, this is not contributing. So, if we equate it to 0, so c_1 is equal to 0. In the second, only this is contributing c_2 into 1, others are not contributing, so c_2 is equal to 0. And the third component gives us c_3 equal to 0. So, this is the only solution possible for this equation to be satisfied. And that is why; we say that the set S consisting of these 3 vectors is linearly independent. So, S is linearly independent set of vectors.

(Refer Slide Time: 06:20)

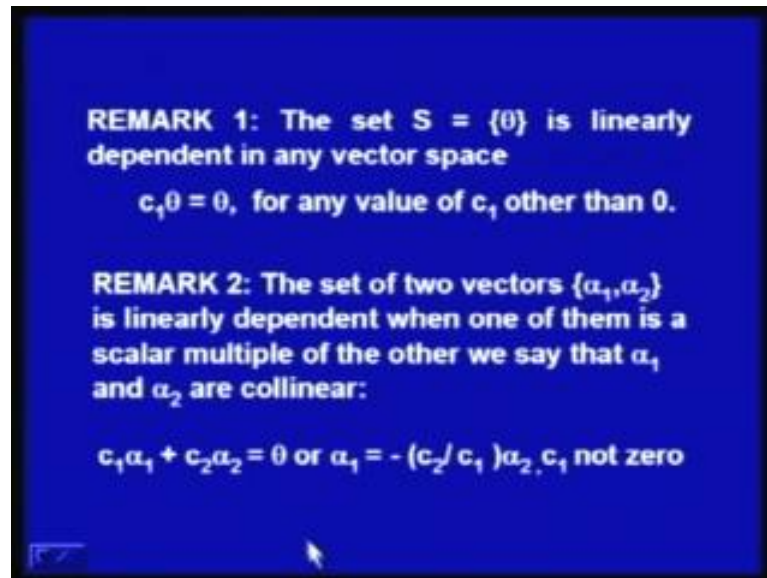

Example: Determine the linear independence / dependence of the set
 $S = \{(0,1), (1,0), (-1,-1)\}$

Solution: Consider the linear combination
 $c_1(0,1) + c_2(1,0) + c_3(-1,-1) = (0,0)$
 $c_2 - c_3 = 0$
 $c_1 - c_3 = 0$
 $c_3 = c_2 = c_1 = K.$
 $c_3 = 1, c_2 = 1, c_1 = 1$
There exist a nontrivial solution of the system.
Linearly dependent

Now, in another example, we have to check, whether the set $(0, 1), (1, 0), (\text{minus } 1, 1)$ is a set of linearly independence or dependent set of vectors. The solution is, we consider the linear combination of these 3 vectors. The combination is $c_1(0, 1) + c_2(1, 0) + c_3(-1, -1)$ and equated it to $(0, 0)$. We equate component wise. So, this will not be contributing. But, this will give us $c_2 - c_3 = 0$ and the second component gives us $c_1 - c_3 = 0$. This will not contribute $c_3 = 0$.

So, we have two equations in three unknown's c_1, c_2 and c_3 . So, the solution of these two equations gives us $c_2 = c_3$, the first equation. $c_1 = c_3$ from the second equation and this can be assigned any arbitrary value K . So, we will have $c_3 = 1, c_2 = 1, c_1 = 1$, when $K = 1$ is a solution of this equation. So, a nontrivial solution is possible. So, there exists a nontrivial solution of the given system. And hence, we say the 3 vectors $(0, 1), (1, 0), (\text{minus } 1, -1)$ in the set S are linearly dependent or the set is the set of linearly dependent vectors.

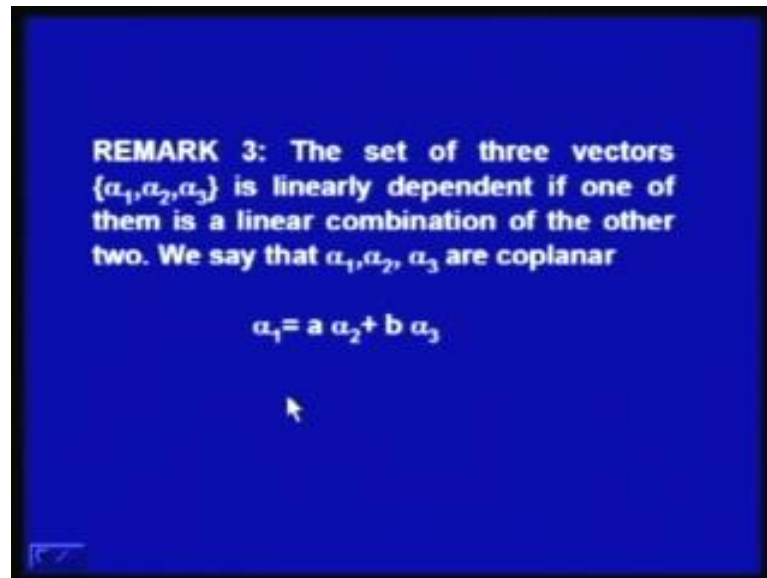

(Refer Slide Time: 08:03)

Now, we are now in a position to make some remarks. So, the remark 1 is, that the set S consisting of a single term 0 , which is additive identity in the vector space is linearly dependent in any vector space. So, whatever be the vector space, this singleton set will be linearly dependent set. And this can be proved very easily. You can see that c_1 into null vector θ is equal to null vector, for any value of c_1 other than 0 .

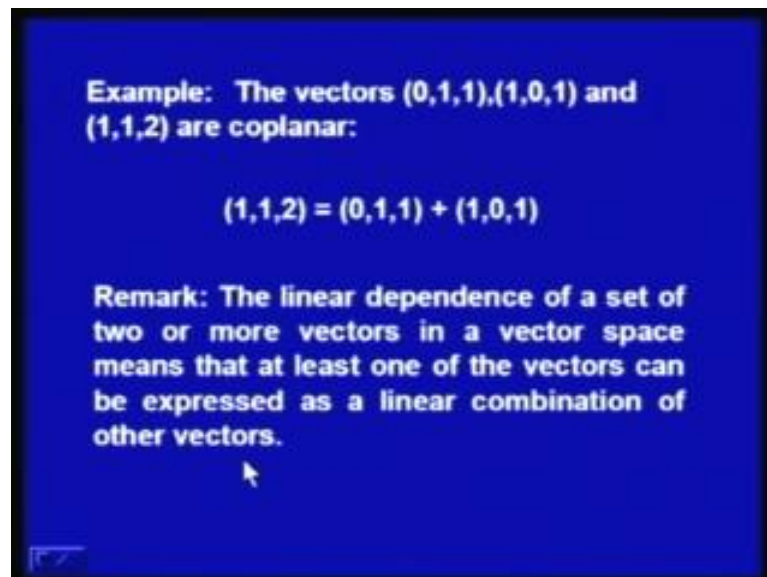

So, the nontrivial solution for this equation exists and that is why; this set is always linearly dependent. In another remark, the set of 2 vectors, α_1 and α_2 , if it is linearly dependent, then one of them is a scalar multiple of the other. And we say that, α_1 and α_2 are collinear. This is proved here. We will have $c_1 \alpha_1 + c_2 \alpha_2$ is equal to null vector, where c_1 and c_2 , if it is c_1 is not 0 . Then, one can write α_1 is equal to minus c_2 by c_1 times α_2 . So, α_1 is written in terms of α_2 , if c_1 is not 0 . Of course, if c_2 is not 0 , then you can write down α_2 is equal to minus c_1 by c_2 into α_1 . So, this way, we can say that the 2 vectors are collinear.

(Refer Slide Time: 09:48)

Similarly, the set of 3 vectors $\alpha_1, \alpha_2, \alpha_3$ is linearly dependent. If one of them is a linear combination of the other two. And in such a case, we say that, the vectors $\alpha_1, \alpha_2, \alpha_3$ are coplanar. Like, I have written α_1 is equal to a times α_2 plus b times α_3 .

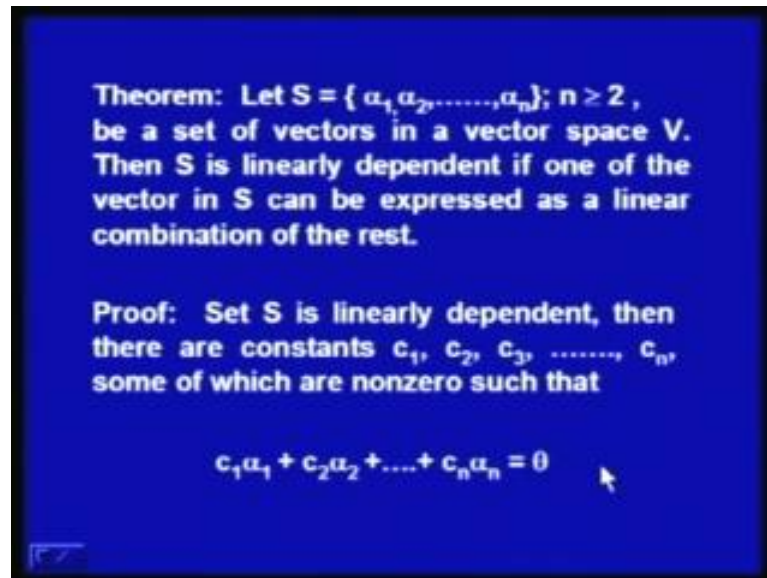

(Refer Slide Time: 10:14)

Now, some examples, the vectors $(0, 1, 1), (1, 0, 1)$ and $(1, 1, 2)$ are coplanar. Let us see we can write down the third vector $(1, 1, 2)$ as a linear combination of the first 2 vectors $(0, 1, 1)$ and $(1, 0, 1)$. You can see, this is 1, so we have

1 on this side. The second is 1, we have 1 here and this 1 plus 1 is 2. So, 1 1 2 is a linear combination of these 2 vectors or we say the 3 vectors (0, 1, 1), (1, 0, 1) and (1, 1, 2) are coplanar in this case. Another remark is the linear dependence of a set of two or more vectors in a vector space means, that at least one of the vectors can be expressed as a linear combination of the other vectors.

(Refer Slide Time: 11:20)

Theorem: Let $S = \{ \alpha_1, \alpha_2, \dots, \alpha_n \}; n \geq 2$, be a set of vectors in a vector space V . Then S is linearly dependent if one of the vector in S can be expressed as a linear combination of the rest.

Proof: Set S is linearly dependent, then there are constants $c_1, c_2, c_3, \dots, c_n$, some of which are nonzero such that

$$c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n = 0$$

Now, this, we write down in form of a theorem. Let S consisting of n vectors, n is greater than equal to 2, be a set of vectors in a vector space V . Then, S is linearly dependent, if one of the vectors in S can be expressed as a linear combination of the rest of the vectors. Now, to prove this, we have given a set S as linearly dependent. Then, there are constants c_1, c_2, c_3, c_n some of which are nonzero. So, we will have $c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n = 0$. So, this is what we have from the very definition of V dependent set S .

(Refer Slide Time: 12:09)

Let $c_k \neq 0$, then

$$c_k \alpha_k = -c_1 \alpha_1 - c_2 \alpha_2 - \dots - c_{k-1} \alpha_{k-1} - c_{k+1} \alpha_{k+1} - \dots - c_n \alpha_n$$

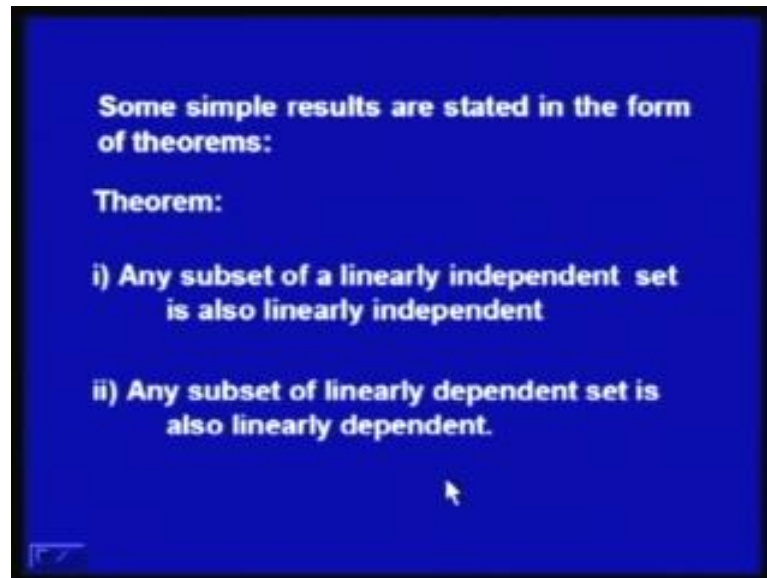

$$\alpha_k = -\frac{c_1}{c_k} \alpha_1 - \frac{c_2}{c_k} \alpha_2 - \dots - \frac{c_{k-1}}{c_k} \alpha_{k-1} - \frac{c_{k+1}}{c_k} \alpha_{k+1} - \dots - \frac{c_n}{c_k} \alpha_n$$

$$\alpha_k = b_1 \alpha_1 + b_2 \alpha_2 + \dots + b_{k-1} \alpha_{k-1} + b_{k+1} \alpha_{k+1} + \dots + b_n \alpha_n$$

Now, we consider c_k to be nonzero. Since, all of the c_k 's are not 0, so let us say c_k is not 0. Then, $c_k \alpha_k$ is equal to minus $c_1 \alpha_1$ minus $c_2 \alpha_2$ minus $c_{k-1} \alpha_{k-1}$ minus $c_{k+1} \alpha_{k+1}$ up to minus $c_n \alpha_n$. So, what I have done is, I had taken $c_k \alpha_k$ on one side and rest of the vectors on the other side. And since c_k is not 0, so I can divide the whole equation by c_k .

So, α_k is equal to minus c_1 by $c_k \alpha_1$ minus c_2 by $c_k \alpha_2$ and up to c_n by $c_k \alpha_n$. And since, minus c_1 and c_k , they are constants. So, I can call them to b_1 and minus c_2 by c_k as b_2 and so on. So, I can express the vector α_k as $b_1 \alpha_1$ plus $b_2 \alpha_2$ plus $b_{k-1} \alpha_{k-1}$ up to $b_n \alpha_n$. By this, I mean to say, that I have expressed α_k as a linear combination of $\alpha_1 \alpha_2 \alpha_{k-1} \alpha_{k+1}$ up to α_n . That is α_k is expressed as linear combination of rest of the vectors.

(Refer Slide Time: 13:39)

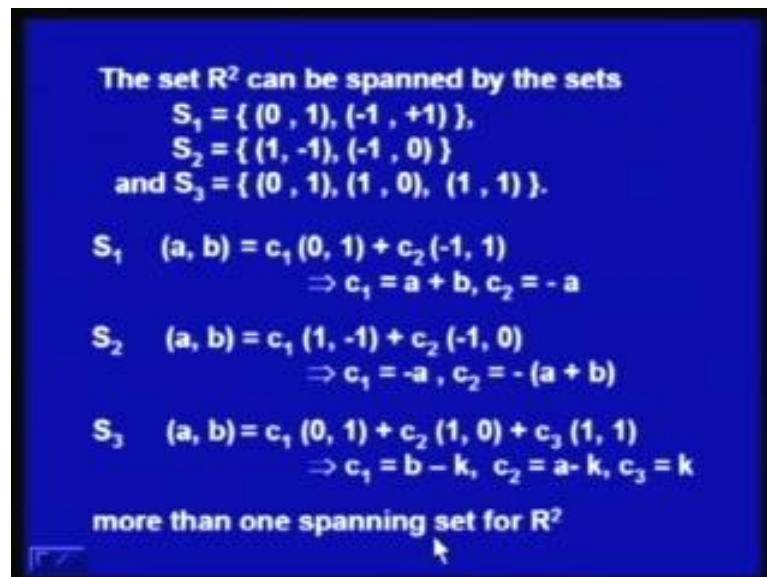

Some simple results are stated in the form of theorems:

Theorem:

- i) Any subset of a linearly independent set is also linearly independent
- ii) Any subset of linearly dependent set is also linearly dependent.

That is, how we proved the theorem. Then, some simple results are stated in the form of theorems. The first theorem is any subset of a linearly independent, set is also linearly independent. And the second is, that any subset of linearly dependent set is also linearly dependent. Now, these are the two exercises user can themselves try.

(Refer Slide Time: 14:06)

The set R^2 can be spanned by the sets

$S_1 = \{ (0, 1), (-1, +1) \}$,
 $S_2 = \{ (1, -1), (-1, 0) \}$
and $S_3 = \{ (0, 1), (1, 0), (1, 1) \}$.

$S_1 \quad (a, b) = c_1 (0, 1) + c_2 (-1, 1)$
 $\quad \quad \quad \Rightarrow c_1 = a + b, c_2 = -a$

$S_2 \quad (a, b) = c_1 (1, -1) + c_2 (-1, 0)$
 $\quad \quad \quad \Rightarrow c_1 = -a, c_2 = -(a + b)$

$S_3 \quad (a, b) = c_1 (0, 1) + c_2 (1, 0) + c_3 (1, 1)$
 $\quad \quad \quad \Rightarrow c_1 = b - k, c_2 = a - k, c_3 = k$

more than one spanning set for R^2

Now, I consider the set R^2 can be spanned by the sets S_1 consisting of 2 vectors. S_2 as another 2 vectors and S_3 consisting of the set of 3 vectors $0, 1, 1, 0, 1$ comma 1 , this can be easily verified. Like, if I consider for the set S_1 , then any vector a, b in R^2 can be

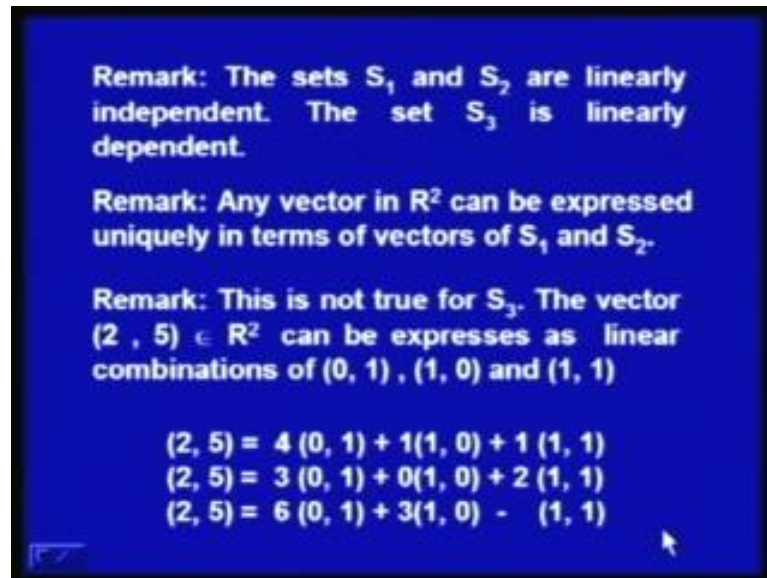

expressed as a linear combination of the vectors of this set $\{0, 1\}$ and $\{-1, 1\}$. So, it is $c_1 \begin{pmatrix} 0 \\ 1 \end{pmatrix} + c_2 \begin{pmatrix} -1 \\ 1 \end{pmatrix}$. Then, c_1 is equal to $a + b$ and c_2 equal to $-a$.

So, since, we can find out c_1 and c_2 in terms of a known vectors a and b . That means this S_1 can span \mathbb{R}^2 , if you consider the set S_2 , in this next example, then a, b equal to $c_1 \begin{pmatrix} 1 \\ -1 \end{pmatrix} + c_2 \begin{pmatrix} -1 \\ 0 \end{pmatrix}$. So, any vector a, b in \mathbb{R}^2 can be expressed as a linear combination of these 2 vectors. We can solve the two equations c_1 is equal to $-a - b$ and c_2 is equal to $-a - b$ is a solution.

So, given a, b we can find out c_1 and c_2 . So, that the vector a, b can be expressed as a linear combination of given 2 vectors. So, we can say that, this set S_2 , can be set or maybe vector space \mathbb{R}^2 can be spanned by this set. Similarly, to see that S_3 spans \mathbb{R}^2 , we again consider any vector in \mathbb{R}^2 , expressed as linear combination of given vectors. So, in this case, we find that c_1 is equal to $b - k$, c_2 is equal to $a - k$ and c_3 is equal to k , where k is an arbitrary value.

The idea in this case is that, we have two equations in three unknowns. So, that is why; we have to introduce an arbitrary constant k over here. And that means, there will be you can choose the value, you can assign the value to this constant k and we will be having different solutions. So, in this case, number of solutions is infinite. And you cannot express a, b in a unique manner in this case. And also another observation here is, that more than one spanning set for \mathbb{R}^2 is possible.

(Refer Slide Time: 17:12)

Remark: The sets S_1 and S_2 are linearly independent. The set S_3 is linearly dependent.

Remark: Any vector in \mathbb{R}^2 can be expressed uniquely in terms of vectors of S_1 and S_2 .

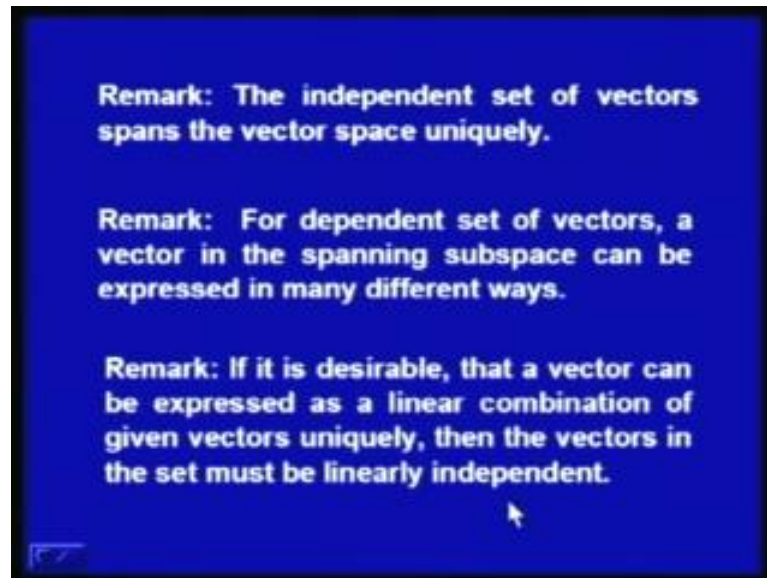

Remark: This is not true for S_3 . The vector $(2, 5) \in \mathbb{R}^2$ can be expressed as linear combinations of $(0, 1)$, $(1, 0)$ and $(1, 1)$

$$(2, 5) = 4(0, 1) + 1(1, 0) + 1(1, 1)$$
$$(2, 5) = 3(0, 1) + 0(1, 0) + 2(1, 1)$$
$$(2, 5) = 6(0, 1) + 3(1, 0) - (1, 1)$$

On the basis of this, we can make some remarks. One can notice that the sets S_1 and S_2 are linearly independent. While, the set S_3 is linearly dependent, also any vector in \mathbb{R}^2 can be expressed uniquely in terms of vectors of S_1 and S_2 . That we have observed. But, if we consider the third set S_3 . Then, this is not true, because the vector, if you consider a specific vector $(2, 5)$ belonging to \mathbb{R}^2 can be expressed as linear combination of these vectors in many different ways.

These are some of the ways, you can find out. You can express 2 comma 5 is 4 times $(0, 1)$ plus 1 times $(1, 0)$ plus 1 times $(1, 1)$. Further $(2, 5)$ can also be expressed as this also $(2, 5)$ can be expressed as $6(0, 1)$ plus $3(1, 0)$ minus $(1, 1)$. This is also possible, because there is arbitrary constant k appearing in the solution of the linear combination. That is why; we are having this particular situation.

(Refer Slide Time: 18:31)

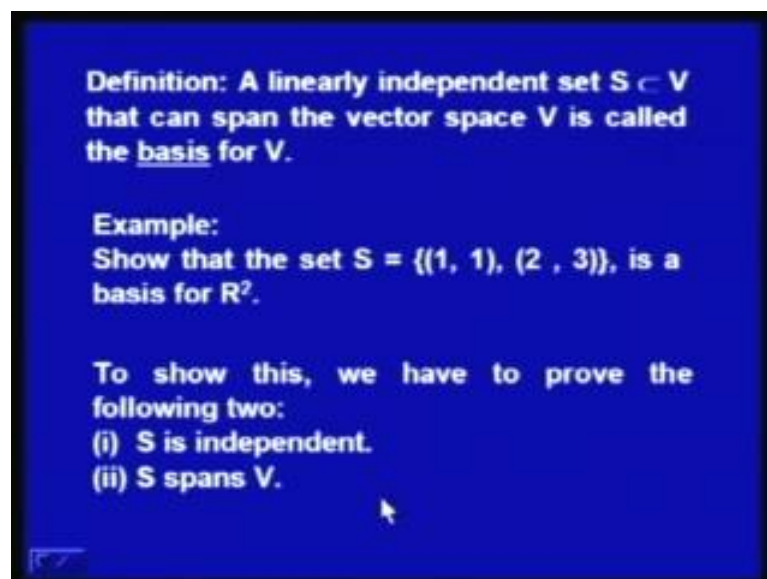

Remark: The independent set of vectors spans the vector space uniquely.

Remark: For dependent set of vectors, a vector in the spanning subspace can be expressed in many different ways.

Remark: If it is desirable, that a vector can be expressed as a linear combination of given vectors uniquely, then the vectors in the set must be linearly independent.

So, on the basis of this, we say that, the independent set of vectors, spans the vector space uniquely. While, if you have dependent set of vectors, then any vector cannot be necessarily represented as linear combination of given vectors. For dependent set of vectors, a vector in the spanning subspace can be expressed in many different ways. So, this is another remark. And finally, it is desirable that a vector can be expressed as a linear combination of given vectors uniquely. Then, the vectors in the set, in the spanning set must be linearly independent.

(Refer Slide Time: 19:20)

Definition: A linearly independent set $S \subset V$ that can span the vector space V is called the basis for V .

Example:
Show that the set $S = \{(1, 1), (2, 3)\}$, is a basis for \mathbb{R}^2 .

To show this, we have to prove the following two:

- (i) S is independent.
- (ii) S spans V .

So, this is observation on this basis. On this, we define basis for a vector space V . So, this is the definition, a linear independent set S , which is subset of V . That can span the vector space V is called the basis for V or this is the definition for basis. Example, show that the set S consisting of $(1, 1)$ and $(2, 3)$ is a basis for \mathbb{R}^2 . Now, to establish this, what we have to do is, we have to show two things. One is that, S is independent and the second is S spans V , when we look at the definition, we have to have a linearly independent set. And then it should span V . So, these two things have to be there.

(Refer Slide Time: 20:23)

S independent: $c_1(1, 1) + c_2(2, 3) = (0, 0)$

$$\begin{aligned} c_1 + 2c_2 &= 0 \\ c_1 + 3c_2 &= 0 \end{aligned}$$

$$\Rightarrow c_2 = 0, \quad c_1 = 0$$

S spans V :

$$c_1(1, 1) + c_2(2, 3) = (a, b) \text{ for all } (a, b) \in V$$

$$\begin{aligned} c_1 + 2c_2 &= a \\ c_1 + 3c_2 &= b \end{aligned}$$

$$\begin{aligned} c_2 &= b - a \\ c_1 &= a - 2(b - a) \\ c_1 &= +3a - 2b \end{aligned}$$

So, let us first check the linear independence of the set. Again, what we have to do is, we have to found the linear combination of the given set $c_1(1, 1)$ plus $c_2(2, 3)$ and equate it to 0. And let us see, what we have next c_1 plus $2c_2$ is equal to 0 and then c_1 plus $3c_2$ equal to 0. So, we have two equations and two unknowns. And the solution is c_2 is equal to 0, if you subtract the 2 we will have c_2 equal to 0. And if you substitute c_2 is equal to 0, say in this equation, then c_1 equal to 0.

So, this system will have only one solution. And that is the trivial solution, c_1 equal to 0 and c_2 equal to 0 and this establishes that S is independent set. The second thing, we have to show for the basis is, that S spans V . For this, we consider a linear combination $c_1(1, 1)$ plus $c_2(2, 3)$. And we show that, any vector (a, b) in V can be expressed as this combination.

So, if you can find out the solution for this equation, then it is possible, otherwise not. So, let us try to solve this system. So, what we have is c_1 plus twice c_2 is equal to a and the second component gives the c_1 plus 3 times c_2 is equal to b . If you solve this, you subtract the 2, it is c_2 is equal to b minus a . And if we substitute it here, then c_1 comes out to be $3a$ minus $2b$. So, given a , b , you can find out c_2 from this equation and c_1 from this equation and this solution will be unique. So, we can say that S spans V . And that establishes that, we have a basis for the given vector space.

(Refer Slide Time: 22:22)

Theorem: Let $S = \{\alpha_1, \alpha_2, \dots, \alpha_n\}$ is a basis for a vector space V . Then the vector v in V can be uniquely represented as a linear combination of vectors of S .

Proof: Let the vector v in V can be represented as a linear combination of vectors in different ways

And
$$v = c_1 \alpha_1 + c_2 \alpha_2 + \dots + c_n \alpha_n$$

$$v = c_1' \alpha_1 + c_2' \alpha_2 + \dots + c_n' \alpha_n$$

Now, the next theorem will say that, S is a set consisting of n vectors. Then, let S is be a basis for vectors space V . Then, the vector V , any vector v in V can be uniquely represented as a linear combination of vectors of S . So, if you have basis, then the vector v in V can the uniquely represented as a linear combination of vectors of S . Now, to prove this, let the vector v in V can be represented as the linear combination of vectors in two different ways.

So, we write down v as $c_1 \alpha_1$ plus $c_2 \alpha_2$ plus $c_n \alpha_n$. At the same time, we have another coefficients c_1 dash c_2 dash c_n dash, etcetera. So, that v is c_1 dash α_1 plus c_2 dash α_2 plus c_n dash α_n .

(Refer Slide Time: 23:25)

$$-v = -c_1'\alpha_1 - c_2'\alpha_2 - \dots - c_n'\alpha_n$$

$$\therefore v + (-v) = \theta = (c_1 - c_1')\alpha_1 + (c_2 - c_2')\alpha_2 + \dots + (c_n - c_n')\alpha_n$$

The vector in the Set S are independent,

$$c_1 - c_1' = c_2 - c_2' = \dots = c_n - c_n' = 0$$

or $c_1 = c_1', c_2 = c_2', \dots, c_n = c_n'$

or the representation is unique.

So, if this is possible, then we can write down, we can multiply the second equation by minus 1. So, we will have minus v is equal to minus c 1 dash alpha 1 minus c 2 dash alpha 2 minus c n dash alpha n. So, if we add the two equations, what we have is, v plus this times minus v is equal to null vector. This is the property of the vector v and theta null vector theta.

Then, c 1 minus c 1 dash alpha 1 plus c 2 minus c 2 dash alpha 2 times alpha 2 plus. The last term is c n minus c n dash alpha c n minus c n dash, times alpha. So, this is equal to theta. Now, we know that alpha 1, alpha 2, alpha n vectors are linearly independent. So, these coefficients have to be 0. That is the basic requirement for the independent set of vectors. So, this is 0, this is 0, this is 0. So, c 1 minus c 1 dash is equal to c 2 minus c 2 dash is equal c n minus c n dash all equal to 0.

And if you further simplify, then c 1 is equal to c 1 dash c 2 is equal to c 2 dash. And finally, c n is equal to c n dash. So, all c i's are equal to corresponding c i dash and that means, they are not different. So, what we can say is, there is only one representation possible. We have started with two different representations. But, ultimately, they come out to be the same. So, we say the representation is unique. So, this establishes the theorem.

(Refer Slide Time: 25:20)

Theorem: The null vector $\theta \in S \subset V$, then S is linearly dependent set.

Any set containing θ is linearly dependent.

Proof: Let $S = \{\alpha_1, \alpha_2, \dots, \alpha_n, \theta\}$
Consider

$$c_1\alpha_1 + c_2\alpha_2 + \dots + \alpha_n c_n + c_{n+1}\theta = \theta$$

For the choice

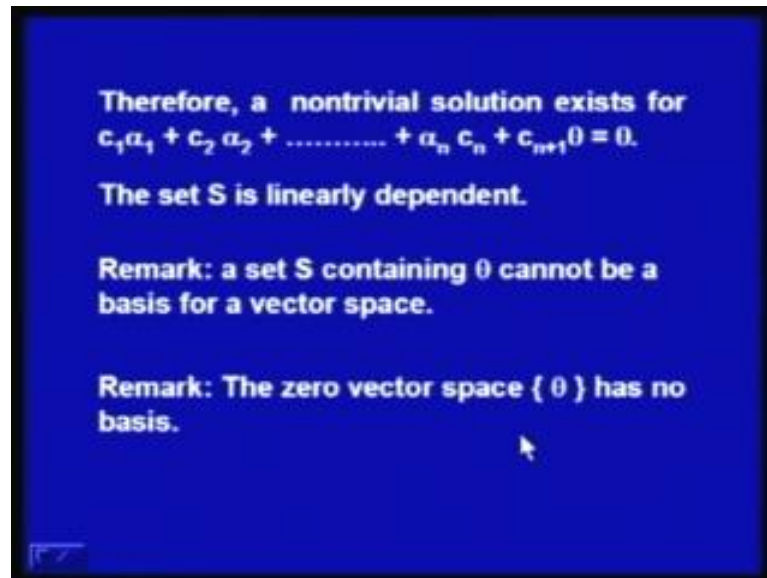

$$c_1 = c_2 = \dots = c_n = 0, c_{n+1} = k \neq 0.$$
$$c_1\alpha_1 + c_2\alpha_2 + \dots + \alpha_n c_n + c_{n+1}\theta = \theta.$$

Now, we have another theorem, which says that, the null vector θ belonging to S , which is subset of V . Then, S is linearly dependent set, by this, I mean to say that, if there is a null vector in the set S , then set S is linearly dependent set. So, any set containing θ is linearly dependent that is another way of writing this theorem. So, let us try to prove this; we consider set of $n + 1$ vectors $\alpha_1, \alpha_2, \dots, \alpha_n$, which are nonzero. And then we add another vector θ into this set.

So, let us consider, whether this set is linearly independent or not. Now, to prove that, this set is linearly dependent or independent, I have to consider this linear combination. So, $c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n + c_{n+1}\theta = \theta$ is equal to the null vector θ . Now, I consider $c_1 = c_2 = \dots = c_n = 0$ and $c_{n+1} = k$. Now, this choice is possible.

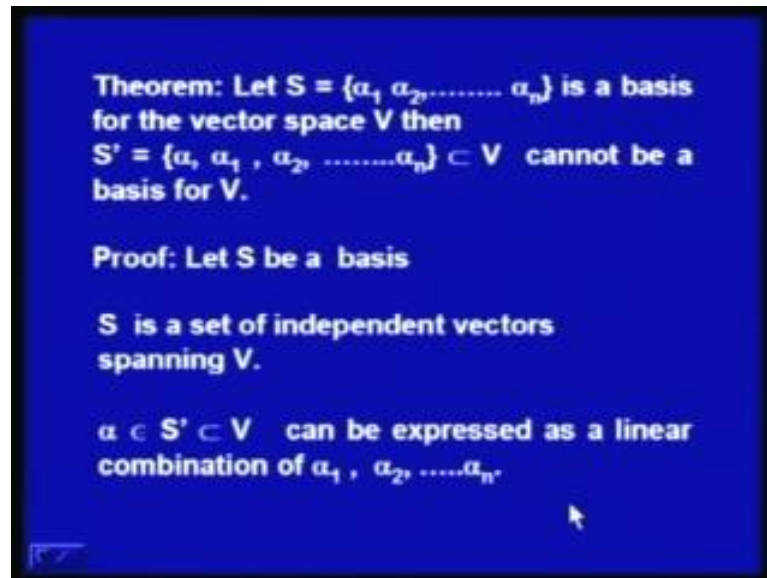

So, if I consider $c_{n+1} = k$ and all this is 0, $k \neq 0$. Then, $c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n + c_{n+1}\theta = \theta$, why because $c_1 = 0$. So, this is this term is not contributing $c_2 = 0$. So, this is not contributing. Similarly, this is not contributing, what remains is, only this term $c_{n+1}\theta = \theta$. So, whatever the c_{n+1} , even, if it is not 0 $c_{n+1}\theta = \theta$. So, I have found one solution in which all c_i 's are 0, but c_{n+1} is not 0. So, I have found one nontrivial solution for this to happen and that is why we have this set $\alpha_1, \alpha_2, \dots, \alpha_n, \theta$ as linearly dependent set.

(Refer Slide Time: 27:31)

Therefore, nontrivial solution exists and it is linearly dependent set. Remark a set S containing 0 cannot be a basis for a vector space. So, this is one observation, which can directly derive from the earlier theorem. Because, by the very definition of basis, the set S has to be linearly independent, only then it can be a basis for a vector space. Now, set is S containing 0 will be linearly dependent, whatever be the vector space. So, it cannot form a basis for a vector space. So, this is about this remark. Then zero vector space 0 has no basis. So, if you consider this set, this is always in a linearly dependent. So, this cannot form of a basis, it has only one set in this. So, we also know that, this set consisting of only 0 forms a vector space. So, this vector space has no basis, this is another remark.

(Refer Slide Time: 28:36)

Theorem: Let $S = \{\alpha_1, \alpha_2, \dots, \alpha_n\}$ is a basis for the vector space V then $S' = \{\alpha, \alpha_1, \alpha_2, \dots, \alpha_n\} \subset V$ cannot be a basis for V .

Proof: Let S be a basis

S is a set of independent vectors spanning V .

$\alpha \in S' \subset V$ can be expressed as a linear combination of $\alpha_1, \alpha_2, \dots, \alpha_n$.

The next theorem says that, if S is a set consisting of n vectors and is a basis for the vector space V . Then, if you add one more vector α in this set and we have another set S' , consisting of $\alpha, \alpha_1, \alpha_2, \dots, \alpha_n$ and still is a subset of V . Then, this S' cannot be a basis for V . So, if you have set S , which is the basis for the vector space V . Then, adding one more vector in S' cannot be a basis for V .

Now, to prove this, let S , be a basis. So, it has to be a set of independent vectors spanning V . That is the definition for basis. And let us say, we have another vector α , which belongs to S' . Since, α also belongs to V S' being a subset of V . Then, α can be expressed as a linear combination of $\alpha_1, \alpha_2, \dots, \alpha_n$. That is a very definition of basis. Any vector α in V must be expressed as a linear combination of vectors of the basis. So, α can be expressed as a linear combination of $\alpha_1, \alpha_2, \dots, \alpha_n$.

(Refer Slide Time: 30:01)

$\alpha = c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n$,
all c_i 's are not zero.

or $c_1\alpha_1 + c_2\alpha_2 + c_n\alpha_n - \alpha = 0$

$\{\alpha_1, \alpha_2, \dots, \alpha_n, \alpha\}$ is linearly dependent set

S' cannot be a basis for V .

By this I mean to say is that alpha is equal to $c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n$, where all c_i 's are not zero. And that means $c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n - \alpha = 0$. That means, $c_1\alpha_1 + c_2\alpha_2 + \dots + c_n\alpha_n - \alpha = 0$, some of them, maybe 0. But, all of them are not 0. So, this set $\alpha_1, \alpha_2, \dots, \alpha_n$ together with this alpha is linearly dependent set. So, there exist linear combinations in which we have nontrivial solution possible. So, this set cannot be linearly independent. And if this is not linearly independent, then this set S' cannot be a basis for V . That is what the theorem is...

(Refer Slide Time: 31:01)

Theorem : $S'' \subset S \subset V$ cannot be a basis for V .

Proof: (by contradiction)

Let us assume S'' be a basis for V .

Let α_1 belong to S but not to S'' .

Then α_1 can be expressed as a linear combination of S'' .

$$\alpha_1 = c_2'\alpha_2 + c_3'\alpha_3 + \dots + c_n'\alpha_n$$

And secondly, if we have S' , which is a subset of S , cannot be a basis for V . So, we prove this by contradiction. So, let us assume that, S' be a basis for V . If S' be a basis for V , S' is a subset of S . So, let α_1 belongs to S , but not to S' . Because, S' is subset of S , there must be exist, some α_1 , which belongs to S , but not to S' .

So, we will have α_1 belonging to S , but not to S' . Then, α_1 can be expressed as a linear combination of S' . So, α_1 can be expressed as a linear combination of vectors of S' . By this, I mean to say that, α_1 is equal to $c_2 \alpha_2 + c_3 \alpha_3 + \dots + c_n \alpha_n$. Because, S' is a basis for vector space V and α_1 belongs to V . It may not belong to S' , but it belongs to V .

So, any vector in V can be expressed as a linear combination of these vectors. So, α_1 is equal to $c_2 \alpha_2 + c_3 \alpha_3 + \dots + c_n \alpha_n$. Where all of them need not be 0 or there maybe some nonzero value c of these coefficients for which this is possible.

(Refer Slide Time: 32:40)

All coefficients are not zero

or $c_2 \alpha_2 + c_3 \alpha_3 + \dots + c_n \alpha_n - \alpha_1 = 0$

Since $S = \{\alpha_1, \alpha_2, \dots, \alpha_n\}$ is a basis for V ,
 $c_2 = c_3 = \dots = c_n = 0$.

$\Rightarrow \alpha_1$ is not a linear combination of vectors of S' .

\Rightarrow it cannot span V .
 \Rightarrow or S' is not a basis.

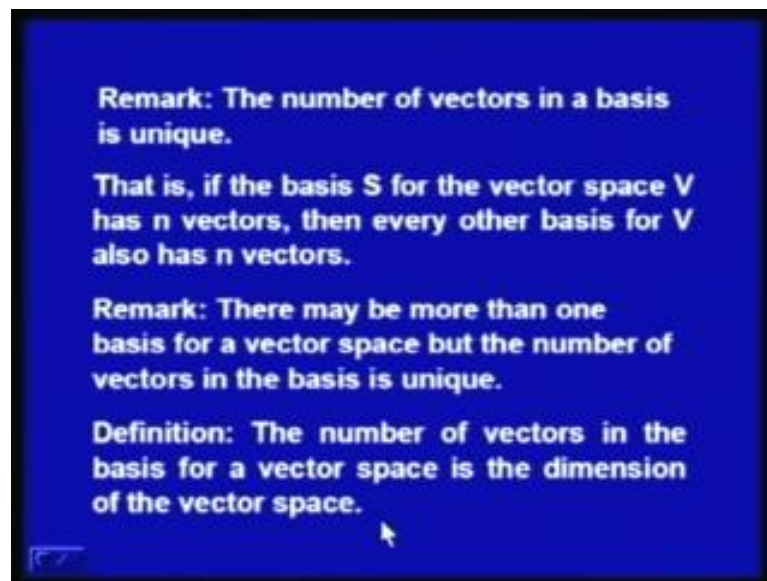

Contradiction

That is we conclude that all coefficients are not zero or $c_2 \alpha_2 + c_3 \alpha_3 + \dots + c_n \alpha_n - \alpha_1 = 0$. If we take α_1 on the same side and by this S is equal to $\alpha_1, \alpha_2, \dots, \alpha_n$ is a basis for V . Since, the basis the, so $c_2 = c_3 = \dots = c_n = 0$. Because, only then it will be a set of

independent vectors and this is set of independent vectors. Because, we have all ready assumed that S is a basis for V .

So, now we have at a contradiction, α_1 is not a linear combination of vectors of S double dash. And that means, S double dash cannot span V or S double dash is not a basis. And that is, how we prove the theorem by contradiction.

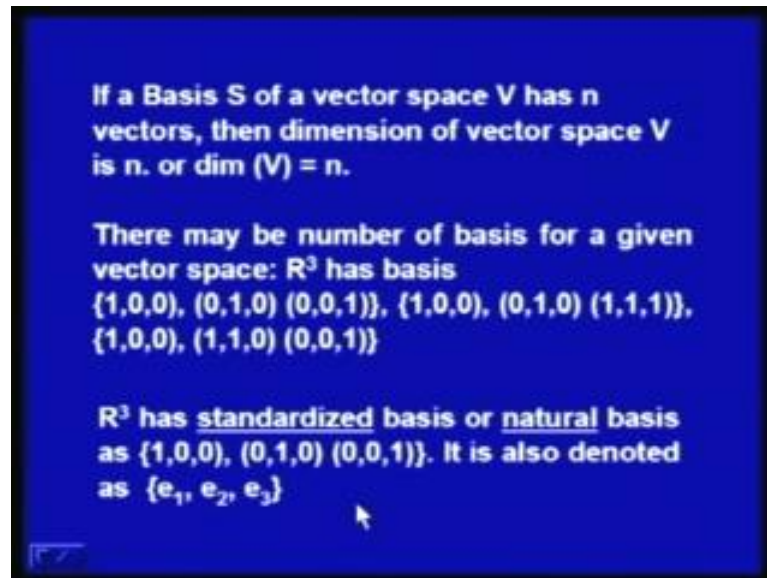

(Refer Slide Time: 33:35)

Then next is the remark, the number of vectors in a basis is unique. That is, if the basis S for the vector space V has n vectors. Then, every other basis for V also has n vectors. In fact, in my earlier two theorems, one theorem says, if I have more than one vector. Then, again it will not form a basis, it becomes linearly dependent. If I have one less vector, then again it will not span the vector space.

So, n is fixed for basis to have n vectors for a vector space V . There may be more than one basis for a vector space. But, the number of vectors in the basis is unique. So, this is what the remark is and on the basis of this. We can now define the dimension of the vector space. We say that the number of vectors in the basis for a vector space is the dimension of the vector space.

(Refer Slide Time: 34:46)

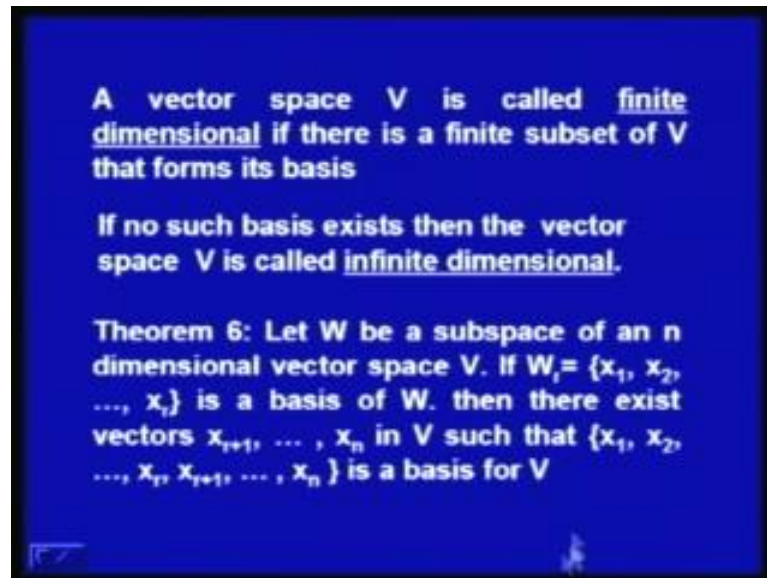

If a basis S of a vector space V has n vectors. Then, the dimension of vector space V is n or we write as dimension of V is equal n . Therefore, there maybe number of basis for a given vector space \mathbb{R}^3 . Like, we will have $(1, 0, 0), (0, 1, 0), (0, 0, 1)$ is a basis for \mathbb{R}^3 . We can have another basis $(1, 0, 0), (0, 1, 0), (1, 1, 1)$ is also basis for \mathbb{R}^3 , $(1, 0, 0), (1, 1, 0), (0, 0, 1)$ is also basis for \mathbb{R}^3 .

So, there maybe number of basis for a given vector space \mathbb{R}^3 . But, the number of vectors in each basis is fixed. This basis also has 3 vectors, this basis also has 3 vectors, this basis also has 3 vectors or we say \mathbb{R}^3 has dimension 3. So, out of these many basis \mathbb{R}^3 has a standardized basis or a natural basis as $1\ 0\ 0, 0\ 1\ 0, 0\ 0\ 1$. It is also the noted as e_1, e_2, e_3 , e_1 is the vector in which the first component is 1, rest of them are 0.

e_2 is the vector in which second component is 1, others are 0, e_3 has the third component 1, others are 0. So, this is the natural basis for \mathbb{R}^3 . So, \mathbb{R}^3 may have number of basis each consisting of 3 vectors, but this special basis. This basis have a special name, we call it standardized basis or natural basis. So, we will have natural basis and there may be other basis for a given vector space \mathbb{R}^3 .

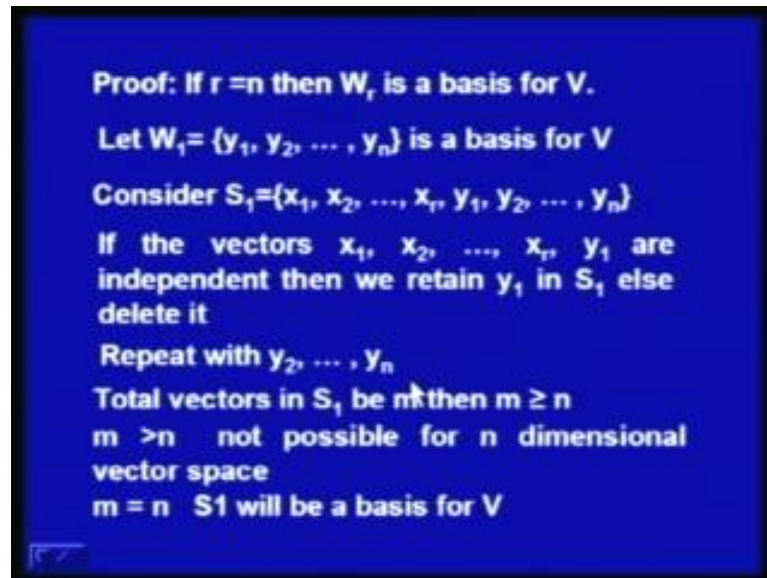

(Refer Slide Time: 36:45)

Another definition a vector space V is called finite dimensional. If there is a finite subset of V ; that forms it is basis. If no such basis exists, then the vector space V is called infinite dimension. On the basis of this, we write down theorem, it says that, like W , be as subspace of an n dimensional vector space V . And if W_r , which is consisting of r vectors x_1, x_2, x_r is a basis of W .

Then, there exist vectors x_{r+1}, \dots, x_n , up to x_n in V , such that, $x_1, x_2, x_r, x_{r+1}, \dots, x_n$ is a basis for V . Now, what we have stated in this theorem is, that we have subspace of an n dimensional vector V , since a subspace. So, it may have less number of vectors, then n . So, this has r vectors x_1, x_2, x_r , then this basis can be expanded to include more vectors from V , then this forms a basis for V . So, we have a basis for subspace, we can extend it to form a basis for V . That is the theorem. So, let us try to prove this result.

(Refer Slide Time: 38:14)

Now, if R is equal to n , then W_r is basis for V . Actually, it is a trivial case, so we do not have to end anything into W_r to form a basis for V . Now, consider the case, when R is less than n . So, for this, we assume a basis for V as W_1 consisting of exactly n vectors y_1, y_2, \dots, y_n . Now, we add these vectors in into the set S_1 . So, now S_1 is $x_1, x_2, \dots, x_r, y_1, y_2, \dots, y_n$.

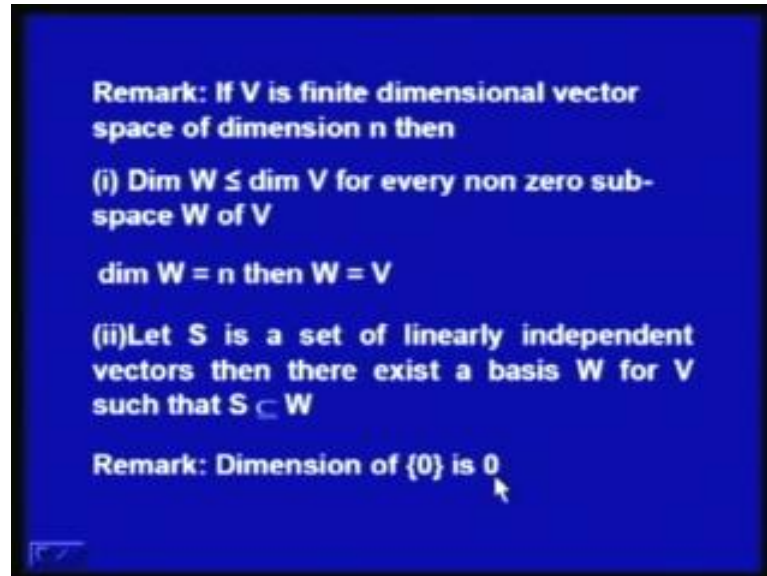

Now, we try to make this S_1 as a basis for V . Actually, this will span the set V , but it may not be a basis. Basis will be, when we have exactly n linearly independent vectors in S_1 . So, we try to obtain linearly independent vectors out of this set. So, that it forms a basis. Now two method is, we consider set of vectors x_1, x_2, \dots, x_r and y_1 only. So, we add only one vector at time in this set.

So, $x_1, x_2, \dots, x_r, y_1$ and we see whether these set of vectors are linearly independent or not. So, we check whether this is linearly independent or not. If y_1 divide with this is linearly independent, then we add y_1 in S_1 , else we delete y_1 from this. So, we will have y_1 in this set, only when this set forms a linearly independent set. Otherwise, we delete y_1 . We repeat this by adding y_2, y_3, \dots, y_n at a time into the set S_1 .

So, we repeat this process with y_2, y_3, \dots, y_n . So, the total vectors in S_1 after this step will be m say that m will be greater than equal to n . But, greater than n is not possible for n dimensional space, because n dimensional space will have at the most n independent

vector. So, n is equal to n is the only possibility and in that case we say S_1 will be a basis for V . So, that is, how we have extended, we set S_1 to form a basis for V .

(Refer Slide Time: 40:53)

Now, if we have a vector space V which is finite dimensional, then dimension of W is less than equal to dimension V for every non zero subspace W of V , so every subspace W of V will have dimension less than equal to dimension of V . And in a special case when dimensional of W is the same as dimension of V , then we say this W will be the same as V vector space V , I suggest that viewers can prove this results.

The second one is let S is a set of linearly independent vectors, then there is exist a basis W for V such that, S is a subset of W . Then, next remark is the dimension of a vector space consisting of only of null vector is 0, because if this space have only zero vector. So, zero vector is always linearly dependent, so we will have it is dimension as zero.

(Refer Slide Time: 42:14)

Fundamental problem of linear algebra:

form 1: Given vector space V , select vectors from V to form its basis.

form 2: construct basis from given set $S \subset V$.

Now, we talk about the fundamental problem of linear algebra, which is given in two different forms. The form 1 suggest that given vector space V , if we select vectors to form a basis for V . The second form is construct basis form given set S , which is a subset of V .

(Refer Slide Time: 42:40)

Example 17: Extend the set $S = \{(1,0,2), (1,1,4)\}$ to form a basis for \mathbb{R}^3 .

Solution:
First check the linear independence of S .
Consider $c_1(1, 0, 2) + c_2(1,1,4) = (0, 0, 0)$

$c_1 + c_2 = 0, c_2 = 0, 2c_1 + 4c_2 = 0$
or $c_1 = 0 = c_2 = c_3$.

linear independence

So, these are two different forms. So, let us try to see with the help of an example. So, extend the set S to form a basis for \mathbb{R}^3 , you can notice that \mathbb{R}^3 is a three dimension. Why, it is three dimension, because in one of my earlier examples, I have considered a

natural basis for \mathbb{R}^3 , which consist of 3 vectors. So, every basis they maybe number of basis for \mathbb{R}^3 , but each basis will have 3 vectors. Now, we have set S which consist of only 2 vectors.

So, if these 2 vectors are linearly independent, then we have to add one more vector from \mathbb{R}^3 . So, that this forms a basis. So, this is how the solution works. So, we first check the linear independence of S, if they are these 2 vectors is independent and then we have to form a basis. We have added one more vector into it to form a basis. So, first check the linearly independent of the set S. We consider the linear combination to be $0c_1 + c_2(1, 0, 2) + c_3(1, 1, 4)$ is equal to $(0, 0, 0)$.

And then from this we get $c_1 + c_3 = 0$ from the first component $2c_2 = 0$ and we will have $2c_1 + 4c_3 = 0$. So, $c_2 = 0$. So, from this $c_1 = 0$ and then from this $c_3 = 0$. So, this will have only a trivial solution possible. So, we can say that the vectors $(1, 0, 2)$ and $(1, 1, 4)$ in the set S are linearly independent. So, the form to it to be a basis for \mathbb{R}^3 we have to add one more vector.

(Refer Slide Time: 44:30)

Basis must have three vectors.

one vector from \mathbb{R}^3 must be added in S so that the extended set forms a basis.

The three vectors must be linearly independent and must span the vector space V.

Consider the span of S

$$(x_1, x_2, x_3) = c_1(1, 0, 2) + c_2(1, 1, 4)$$

or $x_1 = c_1 + c_2, x_2 = c_2, x_3 = 2c_1 + 4c_2$

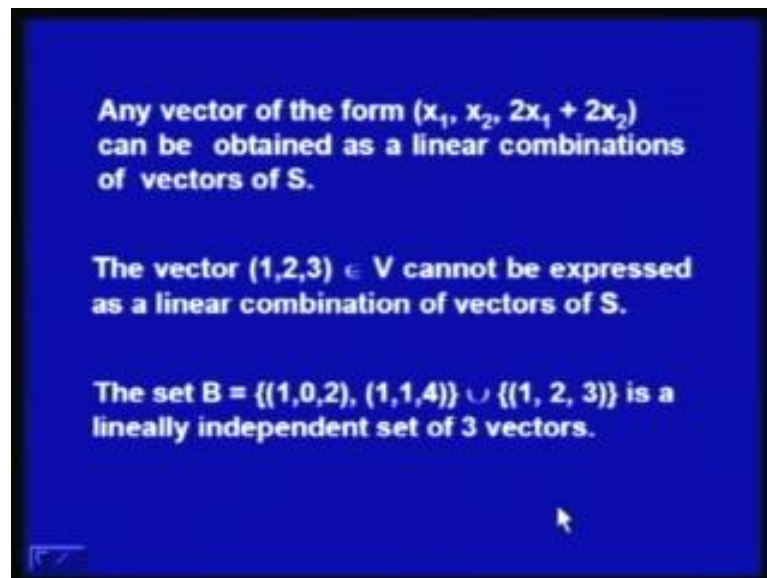

$$c_2 = x_2, c_1 = x_1 - x_2, x_3 = 2x_1 + 2x_2$$

So, one vector from \mathbb{R}^3 must be added in S, so that the extended set forms the basis. The 3 vectors must be linearly independent and must span the vector space. This is the condition for the basis. So, what we do is we add a vector x_1, x_2, x_3 in this. So, we

consider the span of all the vectors of this set S . So, let us say x_1, x_2, x_3 is a vector in the span of S . So, x_1, x_2, x_3 is equal to $c_1(1, 0, 2)$ plus $c_2(1, 1, 4)$.

And that means, if we equate component wise. Then, x_1 is equal to $c_1 + c_2$, x_2 is equal to c_2 and x_3 is equal to $2c_1 + 4c_2$. If you solve these three equations, we will have c_2 is equal to x_2 , c_1 is equal to $x_1 - x_2$ and x_3 equal to $2x_1 + 2x_2$.

(Refer Slide Time: 45:45)

That means, any vector of the form $x_1, x_2, 2x_1 + 2x_2$ can be obtained as a linear combinations of vectors of S . Now, if I consider this vector $(1, 2, 3)$ which clearly belongs to V . Then, it cannot be expressed as a linear combination of vectors of S , because we cannot write down, because this vector $(1, 2, 3)$ is not in this form.

x_1 is 1, x_2 is 2, but $2x_1 + 2x_2$ is actually is not 3. It is that is why $(1, 2, 3)$ does not belong to the span of S and that is why $(1, 2, 3)$ is independent. Then, independent vector and that means, we can add this vector in the set S . And what we have is $(1, 0, 2), (1, 1, 4)$ union $(1, 2, 3)$ is a linearly independent set of 3 vectors. So, we can add this vector into the set S , we form another set B . And now we have set of three independent vectors and this spans. The vector space \mathbb{R}^3 also one can very easily and then we can say that it forms a vector space.

(Refer Slide Time: 47:16)

Verify that $\{(1, 2, 3), (1, 0, 2), (1, 1, 4)\}$ is a basis for V .

Let $(x_1, x_2, x_3) \in V$ can be expressed as a linear combination of these three vectors:

$$(x_1, x_2, x_3) = c_1(1, 0, 2) + c_2(1, 1, 4) + c_3(1, 2, 3)$$
$$\begin{aligned}x_1 &= c_1 + c_2 + c_3 \\x_2 &= c_2 + 2c_3 \\x_3 &= 2c_1 + 4c_2 + 3c_3\end{aligned}$$
$$c_3 = (2x_1 + 2x_2 - x_3)/3, \quad c_2 = (-8x_1 - 2x_2 + 4x_3)/6$$
$$c_1 = (-2x_1 + 2x_2 - x_3)/3$$

Verify that $(1, 2, 3), (1, 0, 2), (1, 1, 4)$ is a basis for V . So, we can consider any arbitrary vector in $V \times 1, x_2, x_3$ and try to express as a linear combination of these 3 vectors. These are three equations if you equate component wise and one can solve these three equations. So, this is the solution, which I have obtained, you can verify that, this is the actually solution of this.

(Refer Slide Time: 47:48)

The Basis is $\{(1,0,2), (1,1,4), (1, 2, 3)\}$.

Remark: Any vector not in the span of S can be included in S to get the basis for V . That means the basis is not unique.

And that means, $(1, 0, 2), (1, 1, 4)$ and $(1, 2, 3)$ forms a basis for \mathbb{R}^3 . Remark any vector not in the span of S can be included in S to get the basis for V ; I have taken $(1, 2, 3)$ in

this set to form a basis. But, any other vector can be taken instead of this vector and that will be a basis. Only, condition is that, this third vector should not be in the span of these 2 vectors, that means basis is not unique.

(Refer Slide Time: 48:21)

Example: Let $W = \{(0,1, 2), (1,1,0), (2,3,2), (1,3,4)\}$. Find the basis for $S[W]$

Solution: It may be noted that $W_1, \{(0, 1, 2)\}$ is independent

Consider the linear independence of the set $W_2 = \{(0,1,2), (1,1,0)\}$

$$c_1(0,1,2) + c_2(1,1,0) = (0,0,0)$$

$$c_2 = 0, c_1 + c_2 = 0, 2c_1 = 0$$

$$\Rightarrow c_1 = c_2 = c_3 = 0$$

In the next example, I will consider these vectors W is equal to $(0, 1, 2), (1, 1, 0), (2, 3, 2), (1, 3, 4)$ find the basis for $S W$. Now, in this example I have 4 vectors in this set W and I have to find the basis for span of W , it is a three dimensional W is a subset of R^3 , because all the vectors belongs to R^3 . So, we have to form the basis for span of W , what I have to do is I will see one by one. Whether, they are independent or not, so starting with $(0, 1, 2)$ in W_1 . So, $(0, 1, 2)$ is always independent.

So, it may be extended to form a basis, we include rather vector $(1, 1, 0)$ from this set in W_2 and let us take whether this forms a basis or not. Again, the procedure is same; you have to find the linear combination. And if you solve this, we will find that, c_1 is equal to c_2 is equal to c_3 equal to 0 is the only solution possible for this. And that means, this also is set of linearly independent vectors.

(Refer Slide Time: 49:45)

For linear dependence / independence of
 $W_3 = \{(0,1,2), (1,1,0), (2,3,2)\}$,
consider
 $c_1(0,1,2) + c_2(1,1,0) + c_3(2,3,2) = (0, 0, 0)$

$$\Rightarrow c_2 + 2c_3 = 0, \quad c_1 + c_2 + 3c_3 = 0,$$
$$2c_1 + 2c_3 = 0$$

$\Rightarrow c_1 = -c_3, c_2 + 2c_3 = 0$
or $c_1 = 1, c_2 = 2, c_3 = -1$ is a solution.
Hence W_3 is linearly dependent set.

Again we repeat with the third vector $(0, 1, 2)$, $(1, 1, 0)$ and $(2, 3, 2)$. This is the W_3 and then we check whether, they are linearly independent or not. So, we consider $c_1(0, 1, 2)$ plus $c_2(1, 1, 0)$ plus $c_3(2, 3, 2)$ is equal to $(0, 0, 0)$ as a linear combination and solving it, we will have these three equations. And the solution is solution for this is c_1 is equal to minus c_3 and c_2 plus twice c_3 is equal to 0.

And this means, c_1 is equal to 1, c_2 is equal to 2, c_3 is equal to minus 1 is the solution for this and that means, W is linearly dependent set. So, these 2 are linearly independent, but when we add this. So, then this becomes linearly dependent set. So, this cannot form a basis, so I drop this.

(Refer Slide Time: 50:46)

Similarly $W_2 = \{(0, 1, 2), (1, 1, 0), (1, 3, 4)\}$ is also linearly dependent set as

$$(1, 3, 4) = (1, 1, 0) + 2(0, 1, 2)$$

There are only two independent vectors

dimension of $S[W] = 2$. $\therefore S[W] = S[W_2]$

for $S[W]$ Basis is $W_2 = \{(0, 1, 2), (1, 1, 0)\}$.

The set W cannot span \mathbb{R}^3 .

Instead I consider this vector $(1, 3, 4)$ is also and one can check whether it is linearly dependent or not. So, if I write down $(1, 3, 4)$ on one side and $(1, 1, 0)$ and 2 time $(0, 1, 2)$ on the right hand side. Then, I can see that $(1, 3, 4)$ can be expressed as a linear combination of these 2 vectors. So, even this is this set is not linearly independent. So, in the given set, we have only two independent vectors and rest of them, they form linearly dependent set.

So, this is, so span of W is of dimension 2. So, $S[W]$ is span of W_2 , the same as span as W_2 . Now, for $S[W]$ basis is W_2 is $(0, 1, 2)$ and $(1, 1, 0)$, so these is the basis. Now, the set W can cannot span \mathbb{R}^3 , because \mathbb{R}^3 is three dimensional and any basis must have 3 vectors, so the set W cannot span \mathbb{R}^3 . So, if we have to find the basis for \mathbb{R}^3 , then we have to add one more vector into this. So, that we have basis.

(Refer Slide Time: 52:09)

The set $\{(0, 1, 2), (1, 1, 0)\}$ is to be extended to include one more vector from \mathbb{R}^3 which is not in $S[W]$, only then it can span \mathbb{R}^3 .
Vectors of $S[W]$ are linear combination of $\{(0, 1, 2), (1, 1, 0)\}$

$\therefore \alpha \in S[W]$ is of the form
 $c_1(0, 1, 2) + c_2(1, 1, 0) = (c_2, c_1 + c_2, 2c_2)$

basis for $\mathbb{R}^3 = \{(0, 1, 2), (1, 1, 0), (1, 5, 1)\}$

Note that $(1, 5, 1)$ is not of the form $(c_2, c_1 + c_2, 2c_2)$

So, let us try to extend this set to have one more vector into it is. So, that R it forms basis for \mathbb{R}^3 , so what I do is I consider $(0, 1, 2)$ and $(1, 1, 0)$ and find the span of this set. So, let us say α belongs to span of W that is α belongs to $S[W]$, then any vector in this will be of this form. So, $c_1(0, 1, 2) + c_2(1, 1, 0)$ will be of the form c_2 comma $c_1 + c_2$ plus c_2 comma twice c_2 .

And that means, basis for \mathbb{R}^3 is $(0, 1, 2)$ comma $(1, 1, 0)$ and one more vector $(1, 5, 1)$ which is not of this form, $(1, 5, 1)$ is not of this form. Note that, $(1, 5, 1)$ is not of this form, c_2 comma $c_1 + c_2$ plus c_2 comma twice c_1 . And that means, this cannot be generated by this. And that means this is independent. So, now I have 3 vectors, which forms a linearly independent set. And that means, this maybe a basis for \mathbb{R}^3 and any linear combination of these vectors will span \mathbb{R}^3 .

In the end, let me summarize what we done today, I have started with the spanning set. The idea was to introduce the concept of linear independence and dependence. And then we have given the definition. And then we have taken some examples and then we established certain results. And on the basis of those results, we have tried to show that, how a given set of linearly independent vectors can be extended to form of a basis for an n dimensional space.

Thank you.
