Lecture - 19
Functions of Complex Variables Part-I

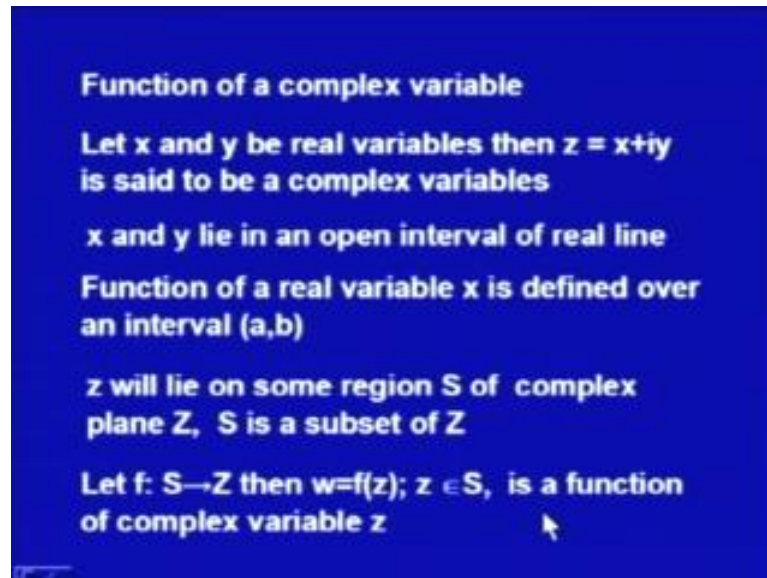

Welcome viewers, today we are discussing Functions of Complex Variables. In this lecture, I will be covering function of a complex variable.

(Refer Slide Time: 00:36)

Then, I will introduce the concept of limit, I will continue with continuity of a complex variable. Then, I will introduce analytic function. And finally, we discuss harmonic functions.

(Refer Slide Time: 00:56)

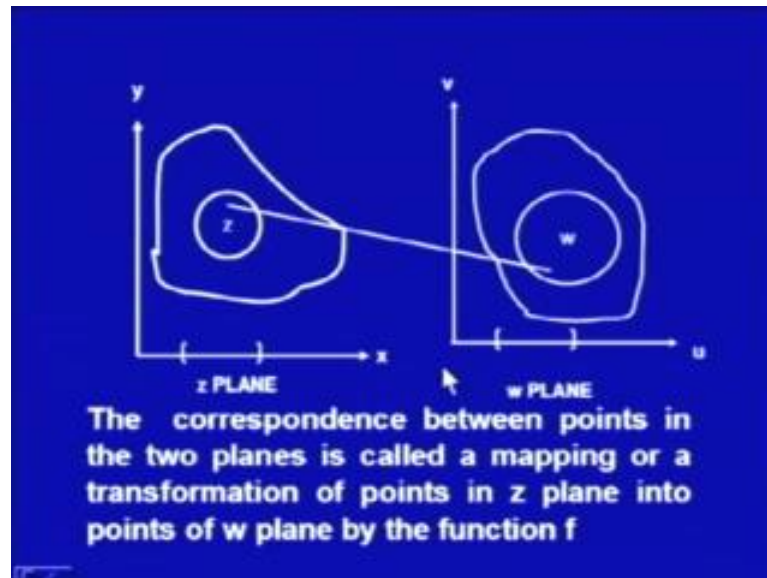

Function of a complex variable
Let x and y be real variables then $z = x+iy$ is said to be a complex variables
 x and y lie in an open interval of real line
Function of a real variable x is defined over an interval (a,b)
 z will lie on some region S of complex plane Z , S is a subset of Z
Let $f: S \rightarrow Z$ then $w=f(z); z \in S$, is a function of complex variable z

First, function of a complex variable, let x and y be real variables. Then, we denote z as x plus $i y$. And we say that, z is a complex variable. We know that, x and y , they are real variables. They lie in an open interval of real line. Then, function of a real variable x is defined over an interval $a b$. However, z will lie on some region S of complex plane and S is a subset of z .

Now, we are in a position to define the function f of a complex variable. Such that, it takes values on the set S and will map to this complex plane z . Then, w is a function of z , where z belongs to the set S . In such a situation, we say that, f is a function of complex variable z .

(Refer Slide Time: 02:01)

Let me illustrate on this diagram, we have real variable x . It lies in interval a b and this is the part of the real line. This is another real variable y and the variable y , will lie on this line and the z will be lying on this plane. This plane is called z plane. By a point on z plane, we will map to a point on w plane, such that w is equal to $f z$. Now, the values z can take in this domain, we call that domain as s .

So, s will map to z and we say w is a function of z . This plane is x and y while this plane is called w plane. Here, z is x plus $i y$, when it map to w , when w is written as u plus $i v$. So, this is real line u and this is real line v . The correspondence between points in the two planes is called a mapping or a transformation of points in z plane into points of w plane by this function f .

(Refer Slide Time: 03:34)

Let u and v be the real and imaginary part of w

$$w=f(z)=u(x,y)+iv(x,y)$$

Complex function $f(z)$ is equivalent to two functions $u(x,y)$ and $v(x,y)$

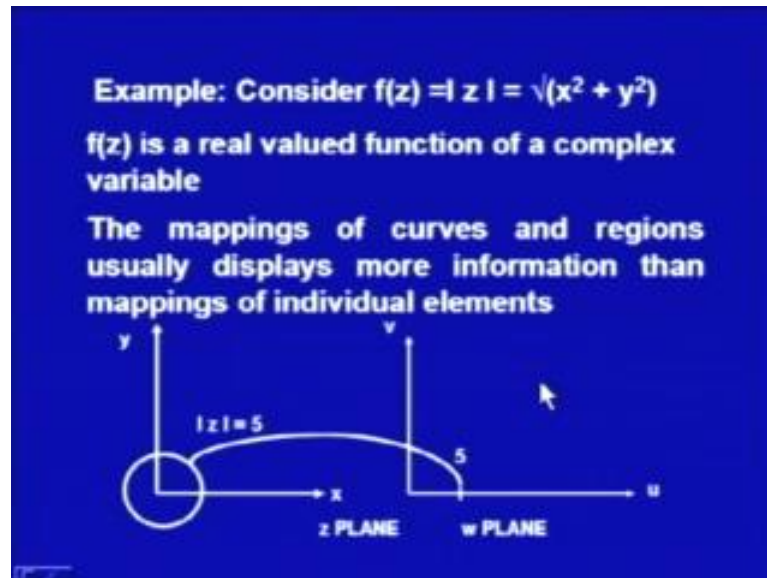

Example: $w = f(z) = 2z^2 + 3z + 5$
 $= 2(x + iy)^2 + 3(x + iy) + 5$
 $= 2(x^2 - y^2) + 3x + 5$
 $+ i(2xy + 3y)$

$$u(x,y) = 2(x^2 - y^2) + 3x + 5$$
$$v(x,y) = 2xy + 3y$$

So, that is how, we introduce concept of functions. Let u and v , be real and imaginary part of w . Then, we write w is equal to fz is equal to u plus $i v$, normally, u is a function of x and y and v is also a function of x and y . So, w also has a real part $u(x,y)$ and imaginary part $v(x,y)$ is also a function of x and y . So, in this sense complex function fz is equivalent to two functions u of x and y and v of x and y . For example, we write w is the function of fz , which is defined as $2z^2 + 3z + 5$.

So, if I write z is equal to $x + iy$, then it is 2 multiplied by $x + iy$ square plus $3x + iy + 5$. Simplifying this, it is $2x^2 - y^2$ the real part coming from this expression. And then plus $3x + 5$, and then i times $2xy + 3y$ coming from this plus $3y$ is the imaginary part. So, this way, we write the function w as consisting of real part as $u(x,y) = 2x^2 - y^2 + 3x + 5$. And the imaginary part $v(x,y) = 2xy + 3y$.

(Refer Slide Time: 05:14)

This is another example. Here, we write the function $f(z)$ as modulus of z . And we write it as under root of x square plus y square. x and y being the real and imaginary part of z , $f(z)$ is a real valued function of a complex variable. Because, this function does not have an imaginary part. So, $f(z)$ maps to real value, that is why; we say this function, $f(z)$ is the real valued function of a complex variable z .

Normally, the mappings of curves and regions, usually displays more information, than mappings of individual elements. So, under this mapping, we write what a particular point will map to this particular point. A particular point in z plane will map to a point in w plane. But, it is more meaningful, if I say this circle $\text{mod } z$ is equal to 5 will map to this point in the w plane. So, this boundary will map to w plane. So, normally mappings of curves and region, they display more information rather than mapping of individual elements.

(Refer Slide Time: 06:29)

Elementary functions of complex variables

The definition of function reduce to the corresponding function of real variable

$f(z) = z^n$ n is a positive integer
 $= z \cdot z^{n-1}$ repeated multiplication

$z^n = (x + iy)^n = r^n (\cos \theta + i \sin \theta)^n$
 $= r^n (\cos n\theta + i \sin n\theta)$

Polynomial function is a linear combination of powers of z

$P(z) = a_0 + a_1 z + a_2 z^2 + \dots + a_n z^n; a_n \neq 0$

Now, will discuss elementary functions of complex variables, we have functions of real variables. We extend those functions to complex variables in such a manner, that when we consider the variable to a real variable. They will become function of a real variable. So, it simply in extension from real domain to complex domain. So, let us say, $f(z)$ is a function of z raise to power n , n is a positive integer. We define this function as z times, z raise to power n minus 1.

The idea is, it is repeated multiplication and when x is a real variable. Then, $f(x)$ becomes x raise to power n with this z square means z multiplied 2 times z raise to power n means z is multiplied n times. Now, z raise to power n can be written as x plus i y raise to power n . And x plus i y in polar form can be written as $r \cos \theta$ plus $i \sin \theta$ in this sense. This number x plus i y raise to power n is r raise to power n multiplied by $\cos n\theta$ plus $i \sin n\theta$ raise to power n .

And further this can be simplified to $r^n \cos n\theta$ plus $i \sin n\theta$. So, z^n can be expressed as real part $r^n \cos n\theta$ plus i times imaginary part $r^n \sin n\theta$. Where the real part u is function of $r^n \theta$ and imaginary part is also function of $r^n \theta$. Once we have defined z raise to power n , we are in a position to define polynomial function. So, polynomial function is a linear combination of powers of z .

And we write it as a_0 plus $a_1 z$ plus $a_2 z^2$ plus $a_n z^n$, where a_n is not equal to 0. So, it is a linear combination of powers of z , means we have z raise to power

0, z raise to power 1 z square z n. And then we have taken their linear combination that is each term is multiplied by a constant, and then added. Here, it is notice that n is not equal to 0, by this, I mean to say that this is a polynomial in degree n. If a n is equal to 0, then this polynomial will be of lower degree

(Refer Slide Time: 09:19)

$$P(z) = \sum_{i=0}^n a_i z^i$$
 A rational function is defined as a ratio of two polynomials

$$w = \frac{p_n(z)}{q_m(z)}$$
 The power series of a complex series is obtained as limit of $P(z)$ as n tends to infinity

$$P(z) = \lim_{n \rightarrow \infty} \sum_{i=0}^n a_i z^i$$

$$S(z) = a_0 + a_1 z + a_2 z^2 + \dots + a_n z^n + \dots$$

In short we write the polynomial $p(z)$ as summation i is equal to 0 to n $a_i z^i$. And this i will take values from 0 to n . From here, we extend to a rational function, a rational function is defined as a ratio of two polynomials. So, if I have two polynomials p and q and $q_m(z)$, then w is $p_n(z)$ divided by $q_m(z)$. Normally, these n and m are different. But, they may be same.

Here, you may note you here the important thing is that q and z is not 0. The power series of a complex series is obtain as limit of $P(z)$ as n tends to infinity. So, we write this expression as $P(z)$ is equal to limit of $a_i z^i$ n tending to infinity. So, this becomes a power series. And we write, it as $S(z)$ is equals a_0 plus $a_1 z$ plus $a_2 z^2$ plus $a_n z^n$ and so on. So, this is a power series, we call it a power series, because each and every terms is express as some power of z .

Now, next is limit of a function of a complex variable, before we proceed to limit of a function of complex variable. I like to review the concept of limit in case of real valued functions real variables.

(Refer Slide Time: 10:56)

Limit of a Function of a real variable

Function $f(x)$ of a real variable x is said to have a limit l as x tends to x_0 if

$f(x)$ is defined in the neighbourhood of x_0 (except possibly at x_0)

for every real number ϵ there exist a such that for every x not equal to x_0

$$|x - x_0| < \delta \Rightarrow |f(x) - l| < \epsilon$$

So, limit of a function of a real variable, let $f(x)$ is a function of a real variable x . Then, we say that, l is the limit of this function $f(x)$ as x tends to x_0 . If $f(x)$ is defined in the neighborhood of x_0 except possibly at x_0 . And then for every real number ϵ there exist a δ . Such that, for every x not equal to x_0 , we have $|x - x_0| < \delta$ implies $|f(x) - l| < \epsilon$. By this I mean to say that, whenever, we are close to x_0 . Then, we are close to l also.

So, if we are close to x_0 and the distance between x and x_0 is δ , then there will be some ϵ . And will be close to $f(x)$, the function $f(x)$ will be close to l . So, that is the meaning of limit of a function of a real variable, closeness to x_0 means closeness to l .

(Refer Slide Time: 12:05)

Limit of a Function of a complex variable

Function $f(z)$ of a complex variable z is said to have a limit l as z tends to z_0 if

$f(z)$ is defined in the neighbourhood of z_0 (except possibly at z_0)

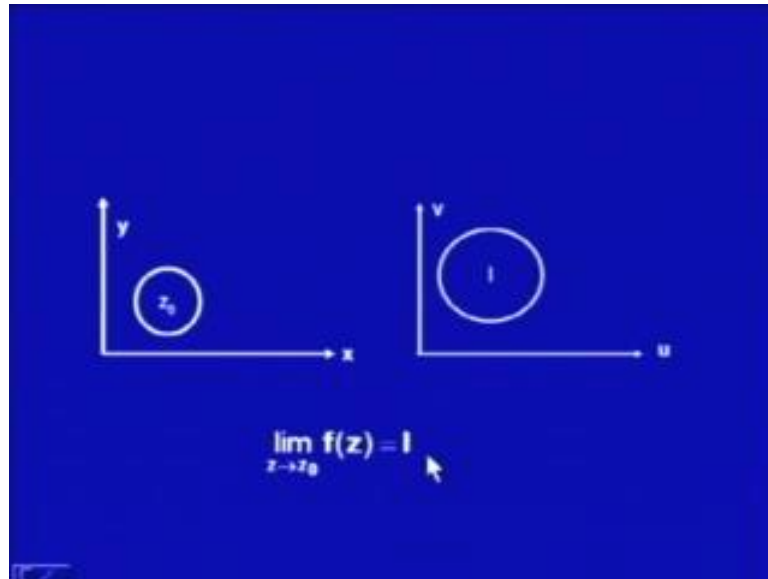

for every real number ϵ there exist a δ such that for every z not equal to z_0

$$|z - z_0| < \delta \Rightarrow |f(z) - l| < \epsilon$$

Now, with this we will go to limit of a function of a complex variable. So, let us say $f(z)$ is a complex variable function z is the complex variable. Then, this function $f(z)$ has a limit l as z tends to z_0 , if it satisfies the two conditions. The first is $f(z)$ is defined in the neighborhood of z_0 accept possibly at z_0 . Further, for every real number ϵ , which has to be positive there exists a positive δ .

Such that, for every z not equal to z_0 , we have modulus of $z - z_0$ is less than δ implies modulus of $f(z) - l$ is less than ϵ . This $|z - z_0| < \delta$ represents a unit circle centered at z_0 . And of radius δ by $|f(z) - l| < \epsilon$ represents circle centered at l and of radius ϵ . So, that means, whenever we have points in the in this circle is that plane. Then, will have points in the circle in w plane.

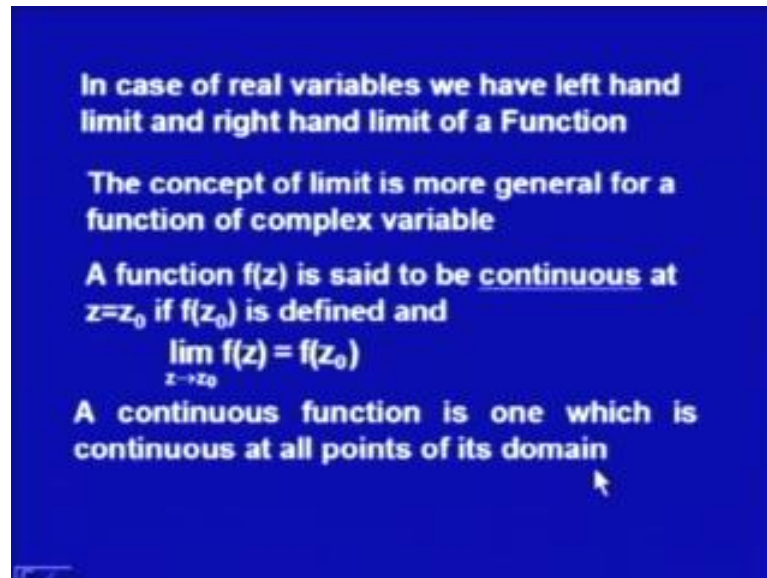

(Refer Slide Time: 13:36)

Let me illustrate this pictorially. So, let us consider z plane and w plane. In z plane, I have a point z_0 and there is a mapping, which maps f of z_0 to l . So, we consider all the points in the δ neighborhood of z_0 . So, whenever we take a point in this neighborhood. So, this is the circle of radius δ centered at z_0 . This is a circle of radius ϵ and centered at l . So, whenever we have a point in this neighborhood of z_0 . Then, correspondingly we have the point f of z in this circle.

So, points here will map to points here. So, points in the δ neighborhood of z_0 will map to points in the ϵ neighborhood of the limit l . That is the meaning of the limit of a function f of z and this we write it as limit of f as z tending to z_0 as l .

(Refer Slide Time: 14:52)

In case of real variables we have left hand limit and right hand limit of a Function

The concept of limit is more general for a function of complex variable

A function $f(z)$ is said to be continuous at $z=z_0$ if $f(z_0)$ is defined and

$$\lim_{z \rightarrow z_0} f(z) = f(z_0)$$

A continuous function is one which is continuous at all points of its domain

In case of real variable, we have left hand limit and right hand limit of a function. However, in case of complex variables, the concept of limit is more general and we will not have only left hand limit. And right hand limit, we have two limit is, in case of real variables. Because, we can approach to the point from left side or from the right side, because, where, the function is defined on an interval, but in case of complex variables.

We can have infinitely many paths to approach to the given point z naught. So, in this sense all the limit is form all the path should be equal. And we say this concept is more general in case of complex variables. A function $f z$ is said to be continuous at the point z is equal to z naught if $f z$ naught is defined and limit of $f z$ as z tending to z naught f of z naught. Now, this definition is also an extension of the definition of continuity of continuous function of real variables. And then a continuous function is one, which is continuous at all points of it is domain.

(Refer Slide Time: 16:18)

A function $f(z)$ is said to be differentiable at $z=z_0$ if

$$f'(z_0) = \lim_{\Delta z \rightarrow 0} \frac{f(z_0 + \Delta z) - f(z_0)}{\Delta z}$$
$$f'(z_0) = \lim_{z \rightarrow z_0} \frac{f(z) - f(z_0)}{z - z_0}$$
$$\left| \frac{f(z) - f(z_0)}{z - z_0} - f'(z_0) \right| < \varepsilon \text{ when } |z - z_0| < \delta$$

The derivative (or differential coefficient) of a function $w=f(z)$ is denoted by dw/dz

$$\frac{dw}{dz} = \lim_{\Delta z \rightarrow z} \frac{\Delta w}{\Delta z}$$

After defining, limit and continuity of a complex variable function. We are now in a position to define differentiability of a complex variables function of f of z . A function f of z is said to be differentiable at z is equal to z_0 . If limit of the expression $f(z_0 + \Delta z) - f(z_0)$ divided by Δz as Δz tending to 0 exists. And then we say this limit is f' of z_0 or derivative of f at z_0 .

If I denotes $z_0 + \Delta z$ as z , then this expression can be written as $f(z) - f(z_0)$ divided by $z - z_0$. The limit of this expression as z tending to z_0 is defining as f' of z_0 . Since, we are defining limit here. So, if we apply the concept of limit. Then, $f(z) - f(z_0)$ divided by $z - z_0$ minus f' of z_0 modulus is less than ε , whenever $|z - z_0|$ modulus is less than δ .

The derivative or we call it as differential coefficient of a function w of $f(z)$ is denoted by dw by dz . This is nothing but, dw by dz . And, we write dw by dz is limit of Δw divided by Δz as Δz tending to 0. We say this is the change in w divided by change in z . So, this Δw divided by Δz , when Δz tending to 0. It is called dw by dz .

(Refer Slide Time: 18:29)

Example: Differentiate $f(z) = z^2$

$$\begin{aligned}\frac{d}{dz}(z^2) &= \lim_{\Delta z \rightarrow 0} \frac{(z + \Delta z)^2 - z^2}{\Delta z} \\ &= \lim_{\Delta z \rightarrow 0} (2z + \Delta z) \\ &= 2z\end{aligned}$$

Let us illustrate this with an example, where $f(z)$ is equal to z square. So, if we have differentiate this then d by dz of z square is equal to z plus Δz whole square minus z square divided by Δz . So, this is the ratio we form, and then we take the limit as Δz tending to 0. So, when, we simplify the numerator, this comes out to be z square and z square cancels out. And what we have is, $2z$ into Δz , which will cancel with this plus Δz square, which out of this Δz square. This Δz will cancel out. And will have only Δz . So, limit of $2z$ plus Δz as Δz tending to 0 means, this is nothing but $2z$ or we say the derivative of $f(z)$ is $2z$.

(Refer Slide Time: 19:29)

Rules for differentiation of a complex variable: Similar to those for real variables

- > Powers of z
- > $f(z) + g(z)$
- > $f(z) \cdot g(z)$
- > $f(z) / g(z) \quad g(z) \neq 0$
- > Chain rule
- > $g(f(z))$

Example : Find derivative of

(a) $f(z) = 3z^4 + 2z^2 + 5$ (b) $(z-3)^4$

(a) $f'(z) = 12z^3 + 4z$ (b) $f'(z) = 4(z-3)^3$

Now, we form the rules for differentiation of a complex variable. These rules are very similar to what we have for real variables. And their proof is also very similar. So, z^n is a power of z . That is z^n derivative of z^n is nothing but n times z^{n-1} . Then, we can have derivative of sum of two functions $f(z) + g(z)$. Then, derivative of this sum is sum of derivatives.

Similarly, we can write a formula for product of two functions. Then, when we have ratio $f(z)/g(z)$, we can differentiate them provided $g(z) \neq 0$. Then, we have chain rule. And it is a composite function; similar formulae can be obtained for these cases, when we have a function of a complex variable. And, they can be used in this example.

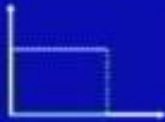

So, if we have to find the derivative of $3z^4 + 2z^2 + 5$. We can consider it to be sum of three functions 1, 2 and 3. And the derivative will be derivative of this plus derivative of this plus derivative of this. We know, how to find derivative of z^4 , and we know how to find derivative of z^2 and so on. So, the derivative of this can be easily formed.

Similarly, in this expression it is $(z-3)^4$. So, write down the derivative, it is a composite function. So, we can find out the derivative of $(z-3)^4$. So, if we solve this the derivative of this function $f(z)$ is $4(z-3)^3$ times derivative of $z-3$, which is one, derivative of this function is simply $4(z-3)^3$.

(Refer Slide Time: 21:48)

Analyticity: A function $f(z)$ is said to be analytic at a point z_0 if it is defined and has derivative at every point in some neighbourhood of z_0

Example: The function $f(z) = w = x-iy$ is not differentiable anywhere

$$f'(z) = \lim_{\Delta z \rightarrow 0} \frac{\overline{(z + \Delta z)} - \bar{z}}{\Delta z} = \lim_{\Delta z \rightarrow 0} \frac{\overline{\Delta z}}{\Delta z} = \lim_{\Delta z \rightarrow 0} \frac{\Delta x - i\Delta y}{\Delta x + i\Delta y}$$

On path 1: $f'(z) = 1$
On path 2: $f'(z) = -1$

Now, we introduce the concept of analyticity. A function $f(z)$ is said to be analytic at a point z_0 , if it is defined and has derivative at every point in some neighborhood of z_0 . So, basically when we say differentiability a function is differentiable at a point, but when we talk about analyticity it has to be differentiable not only at a point z_0 . But, it has to be differentiable in some neighborhood of z_0 .

Example, the function $f(z)$ which is equal to $x - iy$ is not differentiable anywhere. Let us check this $f'(z)$ is obtained as limit of this ratio, this is $\Delta z \Delta f$. So, function $f(z) = \bar{z} = x - iy$. So, $\overline{z + \Delta z} - \bar{z}$ divided by Δz and then we take the limit as Δz tending to 0. So, this is nothing but $\overline{\Delta z}$ divided by Δz and this is equal to limit of $\Delta x + i\Delta y$.

Because, we are taking conjugate, so it is $\Delta x - i\Delta y$ divided by Δz , which is $\Delta x + i\Delta y$. So to take this limit, what we do is, we are here this is my point 0 and this is the point Δz . Now, I can approach to this point in number of ways to get this limit, what I will do is, I will first take this path. On this path, first, we have Δy drop to 0 and then Δx is tending to 0.

So, if I take Δy is equal to 0 in this expression. Then, this and this will cancel out. And, there will be 0 and what is using, Δx divided by Δx which is 1. Whenever, Δx tending to 0, this expression gives me limit as 1. So, on path 1 limit of

this expression that is $f'(z)$ is equal to 1. While, if I consider the second path on which Δx is drop to 0 and then Δy is tending to 0.

So, on path two when this happens; that means, Δx this they becomes 0 and Δy tending to 0. So, this and this are equal. So, this ratio becomes minus 1 and when, we take the limit Δz tending to 0, these remains minus 1. So, we see that along this path limit is comes out to be 1 by along this path limit comes out to be minus 1. But, from the definition of limit both the limit should be the same in whatever way, we have be approach to the point z . So, in this sense, we say limit does not exist. So, $f'(z)$ does not exist and this is true for all values of z . And that is why we say this function is not differentiable anywhere.

(Refer Slide Time: 25:18)

Given $f(z)$ is not differentiable anywhere
 Given $f(z)$ is not analytic anywhere
 Cauchy Riemann Equations
 Let $f(z)$ is analytic in a domain D of z plane
 Let $f(z) = u(x,y) + iv(x,y)$

$$f'(z) = \lim_{\Delta z \rightarrow 0} \frac{f(z + \Delta z) - f(z)}{\Delta z}$$

$$f'(z) = \lim_{\Delta z \rightarrow 0} \frac{u(x + \Delta x, y + \Delta y) - u(x, y)}{\Delta x + i\Delta y}$$

$$+ \lim_{\Delta z \rightarrow 0} \frac{iv(x + \Delta x, y + \Delta y) - iv(x, y)}{\Delta x + i\Delta y}$$

Now, this given $f(z)$ is not differentiable anywhere. So, there is no question that it will be analytic. So, we say $f(z)$ is not analytic anywhere. Now, we discuss Cauchy Riemann equations. And these equations, they are required for checking the analyticity of a given function. So, we first state that Cauchy Riemann equations and then will prove it. So, let $f(z)$ is analytic in a given domain D of z plane. And we write the given function f of z as $u(x,y) + iv(x,y)$; that means, u is the real part and v is the imaginary part.

Then, $f'(z)$ is equal to $f(z + \Delta z) - f(z)$ divided by Δz . The limit of this ration is $f'(z)$ by definition of differentiability. So, we write down $f'(z)$ as limit Δz tending to 0. And $f(z + \Delta z)$ is written as $u(x + \Delta x, y + \Delta y) + i v(x + \Delta x, y + \Delta y)$

$v(x + \Delta x, y + \Delta y)$. So, this is the function of this is written as $u + i v$. So, this is the u part and this is the v part.

Similarly, $f'(z)$ is $u + i v$. So, this is the u part and this is the v part and here x is the function of x and y and we are giving increment. So, $x + \Delta x$ and $y + \Delta y$, but here we have only x and y . So, I have written this into parts first the real part and the second is the imaginary part of f .

(Refer Slide Time: 27:14)

On path 1 $\Delta y = 0, \Delta x \rightarrow 0$

$$f'(z) = \lim_{\Delta x \rightarrow 0} \frac{u(x + \Delta x, y) - u(x, y)}{\Delta x} + \lim_{\Delta x \rightarrow 0} \frac{iv(x + \Delta x, y) - iv(x, y)}{\Delta x}$$

$$f'(z) = \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x}$$

On path 2 $\Delta x = 0, \Delta y \rightarrow 0$ $f'(z) = -i \frac{\partial u}{\partial y} + \frac{\partial v}{\partial y}$

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \quad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}$$

Now, we to take the limit I again consider two paths. First the path 1, that is this green path on which Δy is 0 and Δx is tending to 0. So, along this path $f'(z)$ is written as $u(x + \Delta x, y) - u(x, y)$ divided by Δx and Δz tending to 0 and Δz tending to 0 means Δx is tending to 0. Then, limit Δz tending to 0 for $iv(x + \Delta x, y) - iv(x, y)$ is said to 0 minus i x, y divided by Δx .

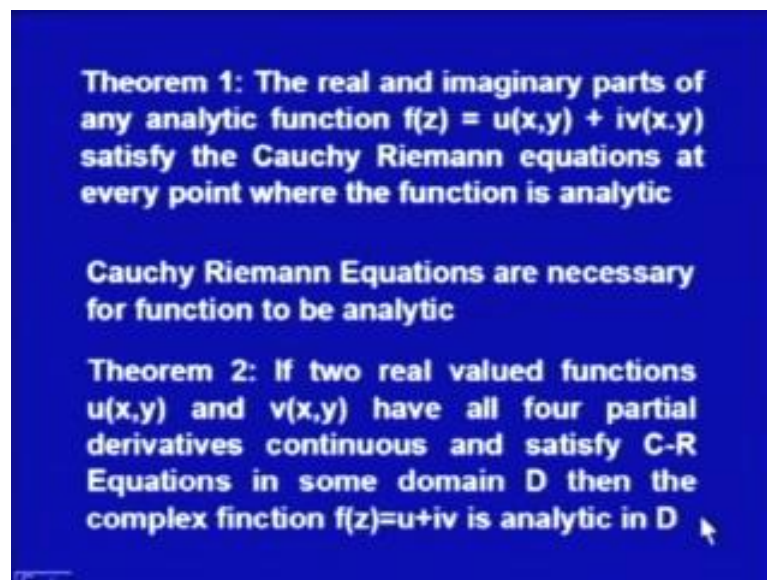

And then we know from the definition of see u is a real variable function of two variables x and y . And this is nothing but the definition of partial derivative of u with the respect to x . And this is partial derivative of v with respect to x . So using that definition, we can write f' of f' dash of z is equal to Δu by Δx plus i times Δv by Δx along this path 1.

Similarly, on path 2 Δx is tend set to 0 and Δy tending to 0. So, if you proceed on same lines then f' dash z comes out to be minus i times Δu by Δy plus Δv by

Δy . So here, I have obtained the limit of two expressions, one along this path another along this path and we have seen along one path it comes out to be this. On the other path, it comes out to be this, if limit has to exist then both the limit is should be same.

So, if we compare these two expressions then for equivalently of them. We should have Δu by Δx the real part of this must be equal to the real part of this. It is Δv by Δy and the comparing the imaginary part here. And the imaginary part here, it is Δu by Δy is equal to minus Δv by Δx . Now, these conditions are called Cauchy Riemann conditions.

(Refer Slide Time: 29:32)

With this we are now in a position to state the theorem. It says that the real and imaginary part of an, any analytic function $f z$ is equal to $u x y$ plus $i v x y$, satisfy the Cauchy Riemann equations at every point where the function is analytic. Now, these Cauchy Riemann equations are necessary function are these Cauchy Riemann equations are necessary for function to be analytic.

Now, the second theorem states that these conditions can be made sufficient. According to this theorem, if two real valued functions $u x y$ and $v x y$ have all four partial derivatives continuous and satisfy C-R equations is some domain D . Then, the complex function $f z$, which is equal to u plus iv then it is analytic in D . So, we require only the continuity of four partial derivatives together with C-R equations.

(Refer Slide Time: 30:51)

Cauchy Riemann Equations are necessary and sufficient

Proof : Let $f(z) = u(x,y) + iv(x,y)$

$$\Delta u = u(x + \Delta x, y + \Delta y) - u(x, y)$$

$$\Delta v = v(x + \Delta x, y + \Delta y) - v(x, y)$$

$$\Delta f = \Delta u + i\Delta v$$

$$\Delta u = \frac{\Delta u}{\Delta x} \Delta x + \frac{\Delta u}{\Delta y} \Delta y + \alpha_1 \Delta x + \beta_1 \Delta y$$

$$\Delta v = \frac{\Delta v}{\Delta x} \Delta x + \frac{\Delta v}{\Delta y} \Delta y + \alpha_2 \Delta x + \beta_2 \Delta y$$

$$\Delta f = \frac{\Delta u}{\Delta x} (\Delta x + i\Delta y) + i \frac{\Delta v}{\Delta x} (\Delta x + i\Delta y) + \delta_1 \Delta x + \delta_2 i \Delta y$$

And then they imply the analyticity. So, in this sense C-R conditions are necessary and sufficient. $\Delta x + i \Delta y + \beta_1 \Delta x + \beta_2 i \Delta y$, so this is nothing but Δz .

(Refer Slide Time: 31:00)

$$\frac{\Delta f}{\Delta z} = \frac{\Delta u}{\Delta x} + i \frac{\Delta v}{\Delta x} + \delta_1 \frac{\Delta x}{\Delta z} + \delta_2 i \frac{\Delta y}{\Delta z}$$

$$\left| \frac{\Delta x}{\Delta z} \right| \leq 1 \quad \left| \frac{\Delta y}{\Delta z} \right| \leq 1$$

Taking limit as $\Delta z \rightarrow 0$

$$\frac{df}{dz} = \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x} + \delta_1 \frac{\Delta x}{\Delta z} + \delta_2 i \frac{\Delta y}{\Delta z}$$

**Derivative exists
Function is analytic**

So, this Δf by Δz is nothing but Δu by Δx plus i times Δv by Δx plus δ_1 times Δx by Δz plus $\delta_2 i$ times Δy by Δz . And since, Δx by Δz , what is Δz , Δz is $\Delta x^2 + \Delta y^2$ Δz^2 is

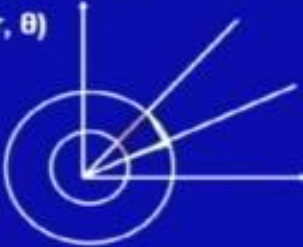

$\Delta x^2 + \Delta y^2$. So, Δx is always smaller than Δz . And that is why; Δx by Δz modulus is less than equal to 1.

Similarly, Δy by Δz is also less than equal to 1 and in this taking the limit as Δz tending to 0. We will have this becoming df by dz is equal to this is Δu by Δx plus this becomes Δv by Δx and plus $\Delta 1$ Δx by Δz plus $2i$ Δy by Δz . And, they tend to 0 and that is why, we say derivative exist and when derivative exist function is analytic. This is coming because the derivatives are these derivatives are continuous. And, that proves the second theorem.

(Refer Slide Time: 32:20)

Cauchy Riemann Equations in polar form

Let $f(z) = u(r, \theta) + iv(r, \theta)$

$$f'(z) = \lim_{\Delta z \rightarrow 0} \frac{u(r + \Delta r, \theta + \Delta\theta) - u(r, \theta)}{(r + \Delta r)e^{i(\theta + \Delta\theta)} - re^{i\theta}}$$

$$+ \lim_{\Delta z \rightarrow 0} i \frac{v(r + \Delta r, \theta + \Delta\theta) - v(r, \theta)}{(r + \Delta r)e^{i(\theta + \Delta\theta)} - re^{i\theta}}$$

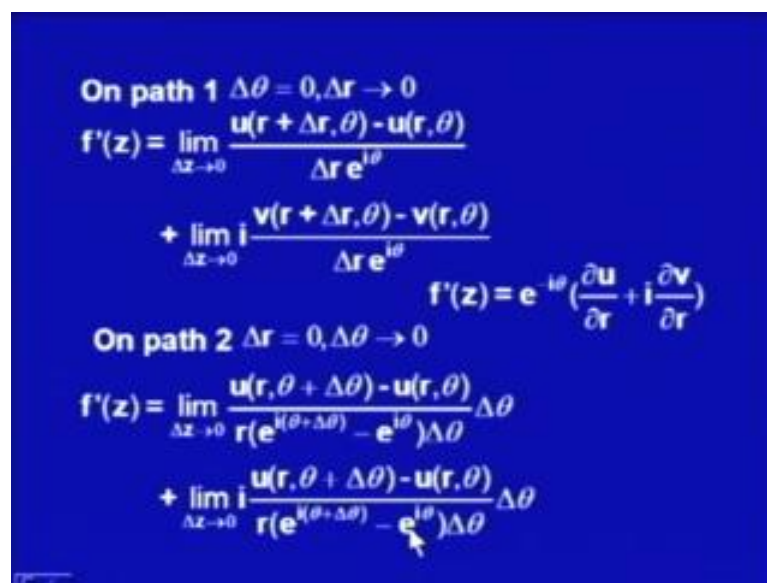

Now, the Cauchy Riemann equations which we have developed they are in Cartesian form. Then, we write z is equal to x plus $i y$, when we write down the function z , when we write down the variable z as $re^{i\theta}$, then Cauchy Riemann equation they are in polar form.

So, to develop Cauchy Riemann equation in polar form, what we do is, we consider z plane and this is our point z and this is the increment here. So, if you have to take limit from this point to this point, then any number of paths can be taken to approach to this point. But, if I consider two different paths, one is along this polar, one along this circular path and then on radial line that is path 1 and the other path is you move along the radial line first and then on this circle.

So, you can approach from this point to this point in two different ways, so if I consider these two different paths. I get the value of the limit and when the two limit is are equated what I get is, C-R equations in polar form.

So, let us consider $f(z)$ is equal to $u(r, \theta) + i v(r, \theta)$ and then I write $f(z + \Delta z)$ is equal to $u(r + \Delta r, \theta + \Delta \theta) + i v(r + \Delta r, \theta + \Delta \theta)$ and this is Δz is written as $r + \Delta r e^{i\theta} + \Delta \theta e^{i\theta}$ this is nothing but Δz . Similarly, I write down the second component and then I take limit along two different paths.

(Refer Slide Time: 34:03)

On path 1 $\Delta\theta = 0, \Delta r \rightarrow 0$

$$f'(z) = \lim_{\Delta z \rightarrow 0} \frac{u(r + \Delta r, \theta) - u(r, \theta)}{\Delta r e^{i\theta}} + \lim_{\Delta z \rightarrow 0} i \frac{v(r + \Delta r, \theta) - v(r, \theta)}{\Delta r e^{i\theta}}$$

$$f'(z) = e^{-i\theta} \left(\frac{\partial u}{\partial r} + i \frac{\partial v}{\partial r} \right)$$

On path 2 $\Delta r = 0, \Delta\theta \rightarrow 0$

$$f'(z) = \lim_{\Delta z \rightarrow 0} \frac{u(r, \theta + \Delta\theta) - u(r, \theta)}{r(e^{i(\theta + \Delta\theta)} - e^{i\theta})\Delta\theta} + \lim_{\Delta z \rightarrow 0} i \frac{v(r, \theta + \Delta\theta) - v(r, \theta)}{r(e^{i(\theta + \Delta\theta)} - e^{i\theta})\Delta\theta}$$

On path 1 $\Delta\theta$ is 0 and Δr tending to 0, we got this expression and from here we can easily see that $f'(z)$ come out to be $e^{-i\theta} \left(\frac{\partial u}{\partial r} + i \frac{\partial v}{\partial r} \right)$. Similarly, on the path 2 Δr is equal to 0 and $\Delta\theta$ tending to 0 and we simplify the expression in this form and from here.

(Refer Slide Time: 34:31)

$$f'(z) = e^{-i\theta} \left(\frac{\partial u}{\partial r} + i \frac{\partial v}{\partial r} \right) \quad f'(z) = -i \frac{e^{-i\theta}}{r} \left(\frac{\partial u}{\partial \theta} + i \frac{\partial v}{\partial \theta} \right)$$
$$\frac{\partial u}{\partial r} = \frac{1}{r} \frac{\partial v}{\partial \theta}$$
$$\frac{\partial v}{\partial r} = -\frac{1}{r} \frac{\partial u}{\partial \theta}$$
$$f'(z) = \frac{\partial u}{\partial x} + i \frac{\partial v}{\partial x}$$
$$f'(z) = -i \frac{\partial u}{\partial y} + \frac{\partial v}{\partial y}$$

We will get $f'(z)$ as this, so $f'(z)$ on path 1 is this $f'(z)$ on path 2 is this. And from here, we can have $\frac{\partial u}{\partial r} = \frac{1}{r} \frac{\partial v}{\partial \theta}$ and from the imaginary parts will get $\frac{\partial v}{\partial r} = -\frac{1}{r} \frac{\partial u}{\partial \theta}$. These are polar forms of C-R equations. These are the Cartesian form of C-R equations, C-R equations we say this is the short form Cauchy Riemann equations or Cauchy Riemann conditions.

(Refer Slide Time: 35:13)

Example: $f(z) = |z|^2$ has derivative at $z=0$

$$f'(z) = \lim_{\Delta z \rightarrow 0} \frac{|\Delta z|^2}{\Delta z} = \lim_{\Delta z \rightarrow 0} \frac{\overline{\Delta z} \Delta z}{\Delta z}$$
$$= \lim_{\Delta z \rightarrow 0} \overline{\Delta z} = \lim_{\Delta z \rightarrow 0} (\Delta x - i \Delta y) = 0$$

$f(z)$ has derivative only at $z = 0$

$f(z)$ is not analytic $z \neq 0$

So, if a function is given $f(z)$ is equal to $|z|^2$ and we have to see, what is its derivative at a given point z is equal to 0. Then, we can make use of the definition of the derivative and we can find its derivative, so let us compute the derivative using the basic definition. So, $f'(z)$ is limit of $\frac{\Delta f}{\Delta z}$ as Δz tends to 0. We can write it like this and Δz and Δz they will tend to they will be cancelled out and what we have is, that $f'(z)$ is equal to 0.

So, and this is independent of path whatever path we choose, Δz tending to 0 this limit will be 0. So, we can say that $f(z)$ has derivative only at z is equal to 0, this will happen only for z is equal to 0, but at no other point, this will happen and we say this function has derivative at z is equal to 0. But, it is not analytic at z is equal to 0.

(Refer Slide Time: 36:23)

Example: Show that $f(z)=2x+ixy^2$ is not differentiable at any point

Solution: For given $f(z)=2x+ixy^2$
 $u=2x$ $v=xy^2$

$u_x=2$ $u_y=0$
 $v_x=y^2$ $v_y=2xy$

Apply C-R conditions $u_x=v_y$ $u_y=-v_x$

C-R conditions are not satisfied
Derivative from two paths are different

Not Differentiable

If you have to show that, this function is not differentiable at any point. We consider it is real path as u is equal to $2x$ and v is equal to xy^2 . Then, we apply Cauchy Riemann equation and from here, we get u_x is equal to u_x means partial derivative of u with respect to x it is 2. And, partial derivative of u with respect to y is 0 for this, partial derivative of v with respect to x is y^2 and for this partial derivative of v with respect to y is $2xy$. And, one can notice that these C-R equations will not be satisfied at any of the points, so we can say the function is not differentiable at any point in the domain.

So, C-R equations are not satisfied, when can very easily check and derivatives from two different paths are different. Because, conditions are not satisfied and that simply means that function is not differentiable.

(Refer Slide Time: 37:31)

Example: Is the following function analytic
 $f(z) = e^x(\cos y + i \sin y)$

Solution: $u = e^x \cos y$ $v = e^x \sin y$

$u_x = e^x \cos y$ $v_y = e^x \cos y$
 $u_x = v_y$

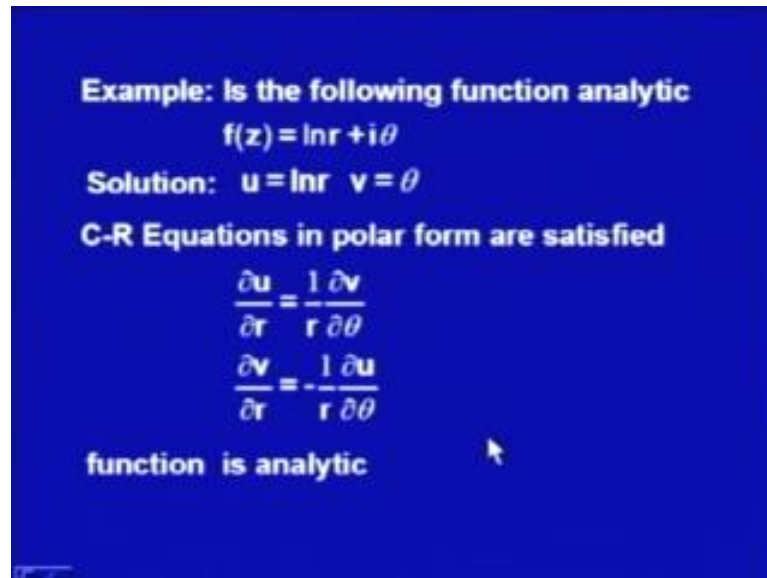

$u_y = -e^x \sin y$ $v_x = e^x \sin y$
 $u_y = -v_x$

C-R conditions satisfied
Partial derivatives continuous
Given function is analytic

In the next example, you have to show whether function is analytic or not, so we consider $f(z)$ is equal to $e^x \cos y + i \sin y$. So, accordingly u is equal to $e^x \cos y$ and the imaginary part v is equal to $e^x \sin y$, we calculate the various derivatives u_x is equal to $e^x \cos y$ plus v_y is $e^x \cos y$ and we can see that u_x is equal to v_y .

Similarly, when you calculate u_y and v_x both the derivatives comes out to be satisfying this condition. So, all the C-R conditions are satisfied and it is irrespective of whatever be the value of x , these conditions are satisfied and we say that this function is analytic. Moreover these functions, these partial derivatives u_x , v_y and u_y and v_x etcetera they are continuous. So, by the help of the two theorems which we have established we can say that this function is analytic. So all these things, I have already explained, so this given function is analytic.

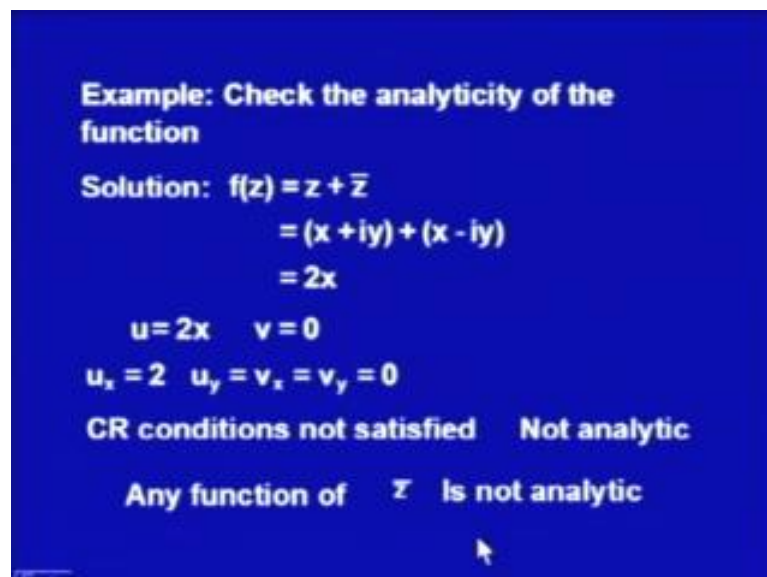

(Refer Slide Time: 38:46)

Example: Is the following function analytic
 $f(z) = \ln r + i\theta$
Solution: $u = \ln r$ $v = \theta$
C-R Equations in polar form are satisfied
$$\frac{\partial u}{\partial r} = \frac{1}{r} \frac{\partial v}{\partial \theta}$$
$$\frac{\partial v}{\partial r} = -\frac{1}{r} \frac{\partial u}{\partial \theta}$$
function is analytic

Now, this example makes use of C-R conditions in polar form, so the question is the following function analytic or not. So, $f(z)$ is equal to $\log R$ plus i theta, so accordingly u is equal to $\ln r$ and v is equal to theta. We make use of polar forms of C-R equations which are given as this and one can check that these conditions are satisfied, this is straight forward. So, function is analytic.

(Refer Slide Time: 39:24)

Example: Check the analyticity of the function
Solution: $f(z) = z + \bar{z}$
$$= (x + iy) + (x - iy)$$
$$= 2x$$

 $u = 2x$ $v = 0$
 $u_x = 2$ $u_y = v_x = v_y = 0$
CR conditions not satisfied Not analytic
Any function of \bar{z} is not analytic

Now in this case, you have to check the analyticity of the function $f(z)$ is equal to z plus \bar{z} . We write down $f(z)$ is equal to z plus \bar{z} as x plus $i y$ plus x minus $i y$, so this comes

out to be $2x$. And accordingly, this function has u is equal to $2x$ by v is equal to 0 . So, when we calculate various partial derivatives u_x comes out to be 2 u_y is equal to v_x is equal to v_y is equal to 0 , all other derivatives are 0 , so this u_x is equal to 2 and v_y is 0 . So, this condition will never be satisfied, so C-R conditions are not satisfied and this function is not analytic.

In fact, we can say CR conditions not satisfied, function is not analytic and we say that any function of \bar{z} is not analytic. Any function which involves \bar{z} that function will not be analytic, like in this case the function is written as z plus \bar{z} , so this function is not analytic.

(Refer Slide Time: 40:37)

Let $f(z) = u(x,y) + iv(x,y)$ be an analytic function

\Rightarrow CR conditions are satisfied

$$\frac{\partial u}{\partial x} = \frac{\partial v}{\partial y} \quad \frac{\partial u}{\partial y} = -\frac{\partial v}{\partial x}$$

$$\frac{\partial^2 u}{\partial x^2} = \frac{\partial}{\partial x} \left(\frac{\partial v}{\partial y} \right) \quad \frac{\partial^2 u}{\partial y^2} = -\frac{\partial}{\partial y} \left(\frac{\partial v}{\partial x} \right)$$

$$\Rightarrow \frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$$

Let $f(z)$ is equal to $u(x,y) + iv(x,y)$ be an analytic function, then CR conditions are satisfied; that means, $\frac{\partial u}{\partial x}$ is equal to $\frac{\partial v}{\partial y}$ and $\frac{\partial u}{\partial y}$ is equal to minus $\frac{\partial v}{\partial x}$. And, when you differentiate this first equation with respect to x partially, then left hand side is $\frac{\partial^2 u}{\partial x^2}$, while right hand side becomes $\frac{\partial}{\partial x} \left(\frac{\partial v}{\partial y} \right)$. And similarly, we differentiate the second equation partially with respect to y , so left hand side gives me $\frac{\partial^2 u}{\partial y^2}$ is equal to minus $\frac{\partial}{\partial y} \left(\frac{\partial v}{\partial x} \right)$.

And, we have to equations if we add them together this becomes $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} = 0$. And since, these derivatives are continuous, so we can say that $\frac{\partial}{\partial x} \left(\frac{\partial v}{\partial y} \right)$ is the same as $\frac{\partial}{\partial y} \left(\frac{\partial v}{\partial x} \right)$.

x, so there will cancel out, so right hand side will be 0. Now, this is the Laplace equation in two variables x and y, so we say u satisfies the Laplace equation in two variables.

(Refer Slide Time: 41:58)

$$\frac{\partial}{\partial y} \left(\frac{\partial u}{\partial x} \right) = \left(\frac{\partial^2 v}{\partial y^2} \right) \quad \frac{\partial}{\partial x} \left(\frac{\partial u}{\partial y} \right) = - \left(\frac{\partial^2 v}{\partial x^2} \right)$$
$$\Rightarrow \frac{\partial^2 v}{\partial x^2} + \frac{\partial^2 v}{\partial y^2} = 0$$

Theorem: The real and imaginary parts of an analytic function in a domain D are solutions of Laplace equation

A harmonic function has continuous second order partial derivatives that satisfy Laplace equation

Similarly, the other partial derivative other function v also satisfies the Laplace equation. So, what we can do is, we first differentiate with respect to delta by delta y, we get this expression. In the second is partially differentiated with respect to x we get this, when you add the two we will have delta 2 v delta x square plus delta 2 v delta y square equal to 0.

And, this means that the real and imaginary parts of an analytic function in a domain D are solutions of Laplace equation, this is an important result. And now, the basis of this we say that harmonic functions has continuous second order partial derivatives that satisfy Laplace equation. So, we define a harmonic function which satisfies the Laplace equation and has second order continuous partial derivatives; that means the analytic function there real and imaginary part of an analytic function will be harmonic functions.

(Refer Slide Time: 43:15)

The real and imaginary parts of an analytic function in a domain D are harmonic functions

u and v are real and imaginary parts of an analytic function they are called conjugate harmonic functions

The functions u and v define a pair of conjugate harmonic functions

Given a harmonic function we can always find its conjugate harmonic function

This is what I have stated; the real and imaginary parts of an analytic function in a domain D are harmonic functions. So, if u and v are real and imaginary parts of an analytic function then they are called conjugate harmonic functions. And finally, the functions u and v define a pair of conjugate harmonic function, we say u is conjugate of v and v is conjugate of u. And this says that u and v will define a pair of conjugate harmonic functions. So, given a harmonic function we can always find its conjugate harmonic function, so if u is given then using CR equations we can find v and if v is given we can find u.

(Refer Slide Time: 44:05)

Example: Show that $u = \ln(x^2 + y^2)$ is harmonic. Find its conjugate harmonic function.

Solution: $u = \ln(x^2 + y^2)$

$$u_x = \frac{2x}{x^2 + y^2} \quad u_y = \frac{2y}{x^2 + y^2}$$
$$u_{xx} = \frac{2(x^2 + y^2) - 4x^2}{(x^2 + y^2)^2} \quad u_{yy} = \frac{2(x^2 + y^2) - 4y^2}{(x^2 + y^2)^2}$$
$$u_{xx} = \frac{2y^2 - 2x^2}{(x^2 + y^2)^2} \quad u_{yy} = \frac{2x^2 - 2y^2}{(x^2 + y^2)^2}$$
$$u_{xx} + u_{yy} = 0$$

This we do in this example, here function u is given as $\ln(x^2 + y^2)$, first we have to show that this function is harmonic and then we have to find its conjugate harmonic function. So, to show that this function is harmonic, one has to show that it satisfies the Laplace equation for this u is $u = \ln(x^2 + y^2)$, so we calculate the derivative u_x which comes out to be $2x$ divided by $x^2 + y^2$.

And, its second derivative u_{xx} if you differentiate it once again, then it is $2x$ times $x^2 + y^2$ minus $2x$ times derivative of this it is $2x$, so this is the numerator divided by denominator $(x^2 + y^2)^2$ that comes out to be the second derivative of u . Simplifying this to u_{xx} comes out to be $2y^2 - 2x^2$ divided by $(x^2 + y^2)^2$.

On the same lines one can differentiate this expression partially with respect to y that gives me u_y as $2y$ over $x^2 + y^2$ and again differentiating partially with respect to y gives me this expression for u_{yy} . And, when you add the $2u_{xx} + u_{yy}$ this comes out to be 0 that simply shows that u satisfies the Laplace's equation.

(Refer Slide Time: 45:41)

The slide contains the following mathematical derivations:

$$u = \ln(x^2 + y^2)$$

$$v_y = \frac{2x}{x^2 + y^2} \quad v_x = -\frac{2y}{x^2 + y^2}$$

$$v(x, y) = 2 \tan^{-1}(y/x) + C_1(x)$$

$$v(x, y) = 2\theta \quad v(x, y) = -2 \tan^{-1}(x/y) + C_2(y)$$

$$f(z) = \ln(x^2 + y^2) + 2i\theta$$

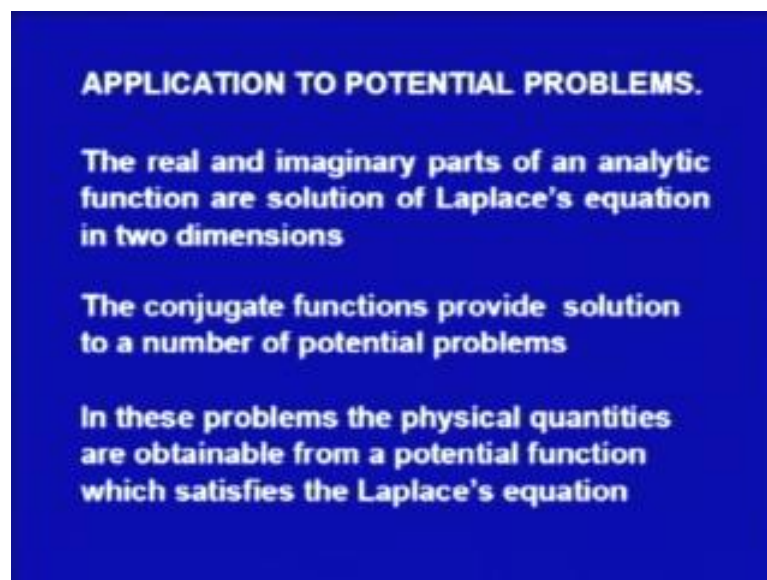

And that shows the first part that u is a harmonic function, once it is established that u is a harmonic function, we can make use of CR equations to find its conjugate. So, u_x we have already computed this will be equal to v_y according to CR equation, so v_y is $2x$ over $x^2 + y^2$.

Similarly, v_x will be minus of u_y which we have computed as this, so using CR equations I have expressions for v_y and v_x . This can be integrated partially with respect to y , see it is a partial derivative with respect to y , so I am treating x as constant while I am getting the derivative.

So, to get v from this expression, what I have to do is, I have to integrate this expression with respect to y keeping x fixed. So, when I integrate this, I get $v_x y$ is equal to $2 \tan^{-1} x/y$ plus constant of integration, now normally we have to have constant of integration C_1 . But in this case, I am getting a constant inside of having a constant I am writing C_1 of as a function of x , because in this integration I am treating x as a constant.

Similarly, when you integrate this partially with respect to x will have $v_x y$ is equal to $-\ln|x^2 + y^2| + C_2 y$. So, if we compare these two we will say that $v_x y$ is equal to $2 \tan^{-1} x/y$ plus $C_1 x$ and $C_2 y$ there should not be functions of x and y , so we have $v_x y$ is equal to $2 \tan^{-1} x/y$. So, once we have obtain $v_x y$ is equal to $2 \tan^{-1} x/y$ I can write down the analytic function $f(z)$ as $\ln|x^2 + y^2| + 2i \tan^{-1} x/y$ the real part and this is the imaginary part. So, it is $2i \tan^{-1} x/y$, so my analytic function is this.

(Refer Slide Time: 47:41)

Next, we will discuss application of complex variables to potential problems. The real and imaginary parts of an analytic function are solution of Laplace equation in two dimensions.

This is what we have seen just now? Now, the conjugate functions provide solution to a number of potential problems in these problems, the physical quantities are obtainable from a potential function, which satisfies a Laplace' equation.

(Refer Slide Time: 48:11)

Fluid Flow:

Consider two – dimensional irrotational motion of an incompressible fluid

The motion is said to be irrotational when $\text{curl } \bar{v} = \bar{0}$.

$\bar{v} = \text{grad } \phi$

$v_x = \frac{\partial \phi}{\partial x}, \quad v_y = \frac{\partial \phi}{\partial y} \quad \dots\dots(1)$

ϕ is called the velocity potential.

$\bar{v} = i v_x + j v_y,$

v_x and v_y are functions of x and y only

Now, there may be number of problems, but I will be considering a problem from fluid flow. So, consider two dimensional irrotational motion of an incompressible fluid. To explain this, the motion is said to be irrotational, when curl of \bar{v} is equal to null vector. From differential calculus, we say that \bar{v} is equal to grade of ϕ \bar{v} is the velocity field here, velocity of fluid flow. Then, this suggest that v_x the x component of velocity will be $\frac{\partial \phi}{\partial x}$ and v_y the y component of velocity will be $\frac{\partial \phi}{\partial y}$. Now, such a function ϕ is called the velocity potential

And, we write velocity \bar{v} as x component in the i direction plus y component in the j direction. So, we write \bar{v} as $i v_x + j v_y$, so v_x and v_y are functions of x and y only, because we are considering two dimensional flow, so they are functions of x and y only no more z is involved in it.

(Refer Slide Time: 49:39)

When the fluid is incompressible, its divergence is zero. This gives

$$\text{div } \vec{v} = 0 \quad \text{or} \quad \frac{\partial v_x}{\partial x} + \frac{\partial v_y}{\partial y} = 0.$$
$$v_x = \frac{\partial \phi}{\partial x}, \quad v_y = \frac{\partial \phi}{\partial y}$$
$$\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} = 0 \quad f(z) = \phi(x, y) + i \psi(x, y)$$

Consider the slope at any point of the curve $\psi(x, y) = c$.

When the fluid is incompressible its divergence is 0, so this gives divergence \vec{v} equal to 0 or $\frac{\partial v_x}{\partial x} + \frac{\partial v_y}{\partial y} = 0$. And since, v_x is equal to $\frac{\partial \phi}{\partial x}$ and v_y is equal to $\frac{\partial \phi}{\partial y}$, that is what we have assumed, then we can substitute these v_x and v_y in this equation and we have $\frac{\partial^2 \phi}{\partial x^2} + \frac{\partial^2 \phi}{\partial y^2} = 0$.

In other words, we say that the velocity potential ϕ is an harmonic function, so if it is an harmonic function, then we can associate a function $f(z)$ which expresses $\phi(x, y) + i \psi(x, y)$. So, $f(z)$ is an analytic function in which the real part is the velocity potential ϕ , but the question is what is this function ψ , we consider the slope at any point of the curve $\psi(x, y) = c$.

(Refer Slide Time: 50:41)

$$\frac{dy}{dx} = \frac{\partial\psi/\partial x}{\partial\psi/\partial y} = \frac{\partial\phi/\partial y}{\partial\phi/\partial x} = \frac{v_y}{v_x}$$

Resultant velocity of a particle is along the tangent to the curve $\psi(x, y) = c$

particle moves on the curve $\psi(x, y) = c$

These curves are called streamlines

$\psi(x, y)$ is stream function

$\phi(x, y) = c'$ are equipotential lines

The two curves intersect orthogonally

And it is computed as $\frac{dy}{dx}$ is equal to $-\frac{\partial\psi}{\partial x} / \frac{\partial\psi}{\partial y}$ which is equal to $\frac{\partial\phi}{\partial y} / \frac{\partial\phi}{\partial x}$ from Cauchy Riemann equations and this is equal to $\frac{v_y}{v_x}$. So, $\frac{dy}{dx}$ is this.

So, we say that the resultant velocity of a particle is along the tangent to the curve $\psi(x, y) = c$. So, we say that a fluid particle moves on the curve $\psi(x, y) = c$ and its velocity is given by $\phi(x, y)$. These curves are called streamlines that is $\psi(x, y) = c$ curves or called streamlines and $\psi(x, y)$ is called a stream function. $\phi(x, y) = c'$ are called equipotential lines, the two curves intersect orthogonally that can be easily be checked.

(Refer Slide Time: 51:47)

The choice of the function $f(z)$ depends on the boundary conditions

Since the flow can't cross a boundary wall, the boundary must be a streamline

FLOW AT A CORNER

The flow in a channel bounded by the axes and the hyperbola $xy = a^2$

Any two of the streamlines could be taken as the bounding walls of the flow

The choice of the function $f(z)$ depends on the boundary conditions. Since the flow cannot cross a boundary wall, the boundary must be a streamline. And on the basis of this, we can solve fluid flow problems, so if we consider flow at a corner. Then, the flow in a channel bounded by the axis and the hyperbola $xy = a^2$ is equal to a square. Any two of the streamlines could be taken as the boundary walls of the flow.

(Refer Slide Time: 52:19)

$f(z) = \phi + i\psi = z^2 = x^2 - y^2 + 2ixy$

And then $f(z)$ is equal to $\phi + i\psi = x^2 - y^2 + 2ixy$ and this function is nothing but z^2 . So, what I have done is here, I have a corner

which is given by coordinate axis and this is the boundary $2xy$ it is nothing but hyperbola. So, the flow is between these boundary this boundary and this boundary.

At inside this boundary, the stream lines are moving along these curves and velocity potential will be given by $x^2 - y^2$. So, these are again these gives us equipotential lines, so if you draw hyperbola's $x^2 - y^2 = a$ then they give us the velocity potential. So, we can see that if the fluid is flowing inside this region, then any particle of the fluid will follow one of these paths. So, that is how we apply theory of complex variables to solve real life problems.

So, with this we have completed this lecture on function of complex variables. In this lecture, I have started with the very definition of the function, then I have introduce the concept of limit and this is done on the basis, what we already know, function of our real variable, and then we have extended the ideas.

Then, we have discuss the continuity after that the differentiability and then I have discussed the motion of analyticity of a complex variable. I have obtain CR equations for checking analyticity of a function, I have given some examples to illustrate the concept of analytic function. And then I have introduce the harmonic function and then some problem and it is application to real life problems that is all for today's lecture.

Thank you.
