Lecture - 13
One Dimensional Heat Equation

Dear viewers the topic of my lecture today is One Dimensional Heat Equation. In my last lecture, we had discuss the one dimensional wave equation and it is solution by the method of separation of variables. The method of separation of variables is also called as the product method. In our lecture today, we shall be discussing the one dimensional heat equation and it is solution by the same method that is the method of separation of variables. We shall consider a uniform bar and the flow of heat in the uniform bar under the assumptions.

(Refer Slide Time: 01:06)

That the sides of the bar are insulated and the sides the loss of heat by conduction or radiation in the bar is negligible.

(Refer Slide Time: 01:17)

Consider the element PQ of the bar of length Δx and area of cross-section A.

The amount of heat flowing into the element across the section at P in time Δt is

$$-K A \left(\frac{\partial u}{\partial x} \right)_x \Delta t,$$

So, let us consider a small element PQ of the bar of length Δx and area of cross section A. Then the amount of heat that flows into the element across the section at the point P in time Δt is given by minus K into A into gradient at x Δu by Δx at x into Δt , where A is the area of cross section at P and K is the thermal conductivity of the material.

(Refer Slide Time: 01:55)

where K is the thermal conductivity and the negative sign is taken because heat flows in the direction of decreasing temperature.

The amount of heat flowing out of the element across the section at Q in time Δt is

$$-K A \left(\frac{\partial u}{\partial x} \right)_{x+\Delta x} \Delta t,$$

The negative sign is taken because the heat flows in the direction of decreasing temperature. The amount of heat that flows out of the other Side of the element PQ that

is across the section at Q in time Δt is then minus K into the gradient at x plus Δx into Δt .

(Refer Slide Time: 02:20)

Hence the amount of heat retained by the element in time Δt is

$$-KA \left\{ \left(\frac{\partial u}{\partial x} \right)_x - \left(\frac{\partial u}{\partial x} \right)_{x+\Delta x} \right\} \Delta t.$$

If ρ be the density of the bar and s its specific heat, the amount of heat required to raise the temperature of the element by Δu is

$$(\rho A \Delta x) s \Delta u.$$

Hence the amount of heat retained by the element in time Δt is the heat that enters the element and minus the heat that leaves the element PQ at Q. So, we have minus K times Δu over Δx at x minus Δu over Δx at x plus Δx multiplied by Δt . Now, the amount of heat returned by the element, I mean raises the temperature of the element PQ.

So, let us say in time Δt the temperature of the element a PQ is raised by say an amount Δu . Then, if ρ is the density of the bar and s its specific heat the amount of heat required to raise the temperature of the element PQ by Δu is ρ into A into Δx into $s \Delta u$.

(Refer Slide Time: 03:18)

Therefore

$$-KA \left\{ \left(\frac{\partial u}{\partial x} \right)_x - \left(\frac{\partial u}{\partial x} \right)_{x+\Delta x} \right\} \Delta t = (\rho A \Delta x) s \Delta u.$$

Dividing both sides by Δx and letting $\Delta x \rightarrow 0$ and $\Delta t \rightarrow 0$, we have

$$K \frac{\partial^2 u}{\partial x^2} = \rho s \frac{\partial u}{\partial t}$$

or

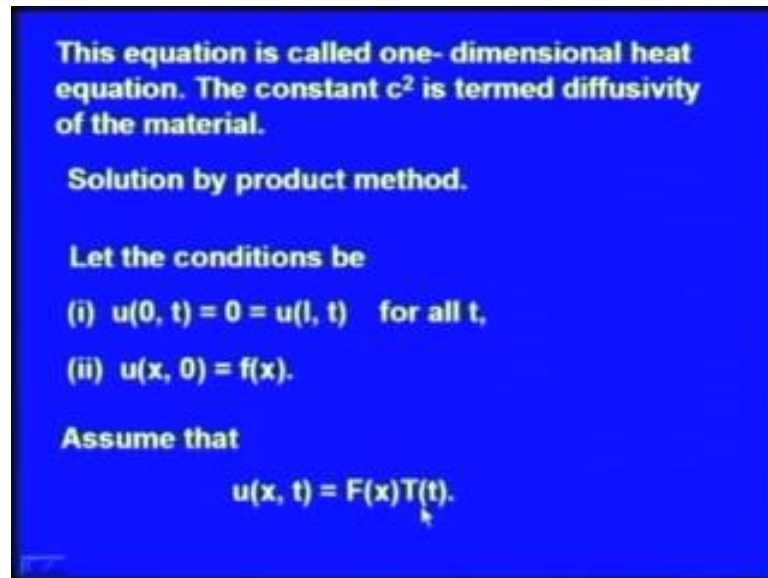

$$\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}, \text{ where } c^2 = \frac{K}{\rho s}.$$

And therefore, we have minus KA into delta u over delta x at x minus delta u over delta x at x plus delta x into delta t equal to rho into A into delta x into s delta u. Now, let us divide both Sides of this equation by delta x and then let delta x and delta t go to 0, we then have; now when you divide this expression by delta x, you have taking minus Sign in Side. We have delta u over delta x at x plus delta x minus delta u over delta x at x divided by delta x gives you delta over delta x of delta u by delta x, that is delta square u by delta x square.

So, the left hand Side becomes K into A into delta square u by delta x square after dividing by delta x and the right hand Side becomes rho into A into s delta u and when you divide by delta t and let delta t go to 0. You have the differential equation delta u by delta t will gain go to delta u over delta t as delta t 10ds to 0 and we shall have rho into s.

So, K into delta square u by delta x square equal to rho s into delta u over delta t or we may say that delta u over delta t is equal to c square times delta square u over delta x square. Because K over s rho is a positive quantity, we can write it as the square of A constant c.

(Refer Slide Time: 04:54)

This equation is called one- dimensional heat equation. The constant c^2 is termed diffusivity of the material.

Solution by product method.

Let the conditions be

(i) $u(0, t) = 0 = u(l, t)$ for all t ,

(ii) $u(x, 0) = f(x)$.

Assume that

$$u(x, t) = F(x)T(t).$$

Now, this equation is called the one dimensional heat equation, the constant c square is termed the diffusivity of the material. We are now going to find the solution of this one dimensional heat equation by product method or the method of separation of variables. So, let us assume the conditions as follows, let us assume that at the end x equal to 0 of the uniform bar, the temperature is 0 for all the time t and same is to at the other end, that is at x equal to l , the temperature is again 0 at for all the time t .

So, the ends of the bar are kept at 0 temperature throughout and the initial condition is assumed as $u(x, 0) = f(x)$, that is the bar is kept at initially is at temperature given by the function $f(x)$. Initial temperature distribution function for the uniform bar is assume to be $f(x)$ here, so as we have done in the case of the vibrating string, here also we assume that $u(x, t)$ the temperature at a distance x from the end x equal to 0. And at end t is assume to be product of two functions, one is a function of x , another one is a function of t .

(Refer Slide Time: 06:22)

Then we have

$$F\dot{T} = c^2 F''T,$$
$$\Rightarrow \frac{\dot{T}}{c^2 T} = \frac{F''}{F} = \text{a constant, say, } K.$$
$$\Rightarrow \dot{T} - Kc^2 T = 0$$

and $F'' - KF = 0$

Case 1. If $K = 0$ then $F'' - KF = 0$

$$\Rightarrow F(x) = ax + b.$$

Let us substitute $u(x, t)$ equal to $f(x)T(t)$ into $T(t)$ in the one dimensional wave equation, we then have $F\dot{T} = c^2 F''T$, where $T\dot{}$ denotes the partial derivative with respect to T . In fact, here it is the T is the function of just one variable T , so it is ordinary derivative. So, $T\dot{}$ denotes the derivative of T with respect to T and $\dot{}$ denotes the derivative of F with respect to x , F'' means $d^2 F$ over dx^2 .

Now, let us separate the variables here we can write this equation also as $\frac{\dot{T}}{c^2 T} = \frac{F''}{F}$. Now, let us again the as just as in the case of the vibrating string, here also we can see that $\frac{\dot{T}}{c^2 T}$ is a function of T alone, while $\frac{F''}{F}$ is a function of x alone and they will be equal if and only if each one is equal to a constant. So, $\frac{\dot{T}}{c^2 T}$ is a constant, $\frac{F''}{F}$ is a constant and they are equal, so they equal to a constant say K .

Now, this leads us to two differential equations, ordinary differential equations $\dot{T} - Kc^2 T = 0$. It is differential equation ordinary differential equation of order one and another one $F'' - KF = 0$ which is an ordinary differential equation of order 2. We follow the same procedure to arrive at which value of K will give us the solution of the problem; we start with K equal to 1 with K equal to 0.

So, K is 1, if K is equal to 0, then $F'' - KF = 0$ reduces to $F'' = 0$; that means, $d^2 F / dx^2 = 0$. When, we integrate it twice with respect to x , we arrive at the general solution of $F'' = 0$ as $F(x) = ax + b$.

(Refer Slide Time: 08:32)

Since $u(0, t) = 0 = u(l, t)$ for all t and
 $u(x, t) = F(x)T(t)$,
 we have
 $F(0)T(t) = 0 = F(l)T(t)$
 $\Rightarrow F(0) = 0 = F(l)$. Hence $F(x) = ax + b$ implies
 $\Rightarrow a = 0 = b$ and therefore $F \equiv 0$.
 Consequently, $u \equiv 0$ (inadmissible).

Now, let us use the given boundary conditions, that is $u(0, t) = 0$ and $u(l, t) = 0$ for all t , then and also that $u(x, t) = F(x)T(t)$. So, then we shall have $F(0)T(t) = 0$ and $F(l)T(t) = 0$ for all the time T and this will imply that $F(0)$ has to be 0 and $F(l)$ has to be 0. Because, otherwise if you assume that $T(t)$ is equal to 0 then $u(x, t)$ will be 0 for all values of x and t and which is an uninteresting case.

So, $F(0)$ has to be 0 and $F(l)$ also has to be 0 and if you make use of these two values, that is $F(0) = 0$ and $F(l) = 0$ in $F(x) = ax + b$, what you get is $F(0) = 0$ gives you $b = 0$ and $F(l) = 0$, then gives you $al = 0$. So, a is equal to 0 and therefore, a and b both are zeros and hence we get F as identically 0, when F is identically 0, clearly u is also identically 0, which is inadmissible. So, u is consequently u is identically 0, which is inadmissible and therefore, the case K is equal to 0 is discarded.

(Refer Slide Time: 10:10)

Case 2. Let $K > 0$, say $K = \mu^2$.

Then $F'' - KF = 0 \Rightarrow F'' - \mu^2 F = 0$.

Hence $F(x) = A e^{\mu x} + B e^{-\mu x}$

Now, $F(0) = 0 \Rightarrow A + B = 0$
and $F(l) = 0 \Rightarrow A e^{\mu l} + B e^{-\mu l} = 0$.

From these equations we have

$$B (e^{\mu l} - e^{-\mu l}) = 0.$$

If $(e^{\mu l} - e^{-\mu l}) = 0$ then $\mu = 0$ which makes $K=0$ which is not possible.

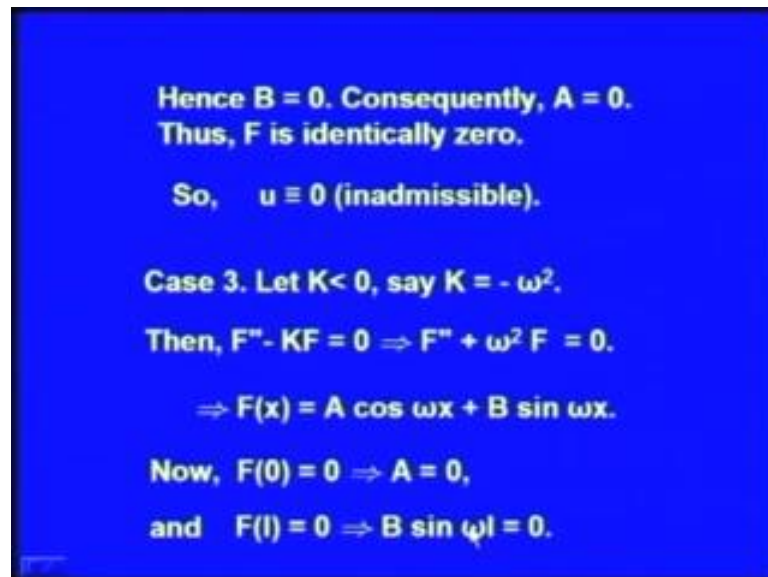

Let us, as now consider the case, when k is a positive constant, we may write it then K equal to μ square, with equal to μ square the second order differential equation $F'' - K F = 0$, implies $F'' - \mu^2 F = 0$ and this is homogeneous differential ordinary differential equation of order 2. So, complementary function for this will be $m^2 - \mu^2 = 0$ and therefore, the values of m will be $\pm \mu$, which are both real and distinct.

And therefore, the complementary function will be $A e^{\mu x} + B e^{-\mu x}$ particular integral is 0 here, because the right hand side of the differential equation is 0. So, general solution of the differential equation is then given by $F(x) = A e^{\mu x} + B e^{-\mu x}$. Now, making use of the conditions on F that is $F(0) = 0$ and $F(l) = 0$, we arrive at two conditions involving A and B , one is $A + B = 0$, another one is $A e^{\mu l} + B e^{-\mu l} = 0$.

Now, when you solve these two equations, what you do is put $A = -B$ in this equation, second equation reduces to $B (e^{\mu l} - e^{-\mu l}) = 0$. Now, either $B = 0$ or $e^{\mu l} - e^{-\mu l} = 0$, in case we take $e^{\mu l} - e^{-\mu l} = 0$, we will have $e^{2\mu l} = 1$, which implies that μ is equal to 0.

And, when μ is equal to 0, K being equal to μ square gives us K equal to 0, the case K equal to 0, we have already resolved, we have seen that it is inadmissible. So, μ equal to 0 is not possible and therefore, A B has to be equal to 0. So, when B is equal to 0 A plus B equal to 0 gives us A equal to 0 and hence again F is identically 0.

(Refer Slide Time: 12:29)

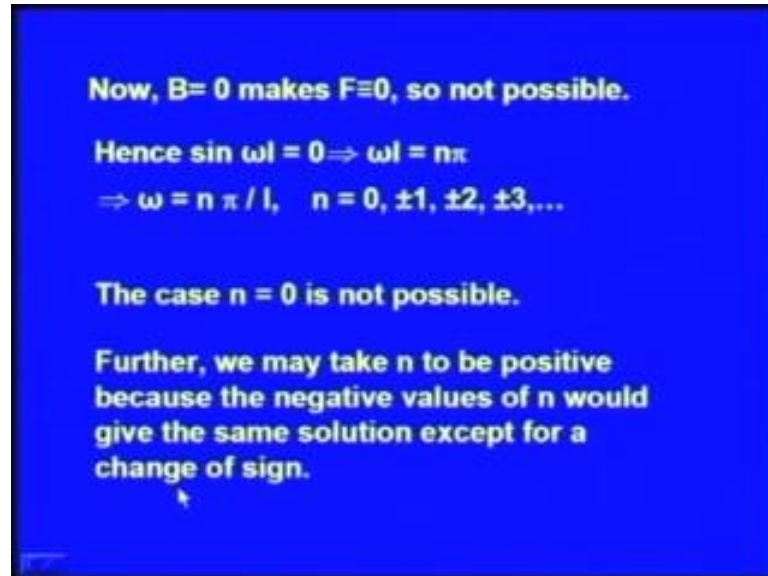

And, when F is identically 0, naturally u is also identically 0, which is inadmissible, so this case is also discarded. Let us, consider the third case, where K is a negative real constant, so let k is less than 0, then we may write it as K equal to minus omega square. Now, when F double dash minus $K F$ equal to 0 with K equal to minus omega square becomes F double dash plus omega square into F equal to 0.

And, we know that this differential equation will give us the auxiliary equation as m square plus omega square equal to 0 and the roots of the auxiliary equation will then be plus minus i omega. So, the complementary function would be $A \cos \omega x$ plus $B \sin \omega x$, particular integral is 0, because the right hand Side of these differential equation is 0, it is homogeneous. And so $F x$ being the sum of complementary function in particular integral will be $F x$ equal to the complementary function, that is $A \cos \omega x$ plus $B \sin \omega x$.

Now, let us use the conditions on F , that is $F 0$ is equal to 0, $F 0$ is equal to 0 gives you when you put x is equal to 0 here, $\sin 0$ zero. So, this term vanishes and we have the right

hand Side s A only. So, F 0 equal to 0 gives A equal to 0 and when you put A equal to 0 here and x equal to l, then F l equal to 0 gives you B sin omega l equal to 0.

(Refer Slide Time: 14:11)

Now, B sin omega l equal to 0 in that if we take B as 0 then A and B both being 0 makes F identically 0, which is not possible as we have seen earlier also. So, we have to take sin omega l as 0, when sin omega l as 0, clearly omega l is equal to n pi and so omega is equal to n pi over l, where n takes all integral values, that is n is equal to 0 plus minus 1, plus minus 2, plus minus 3 and so on.

Now, when you take n as 0 here, means we are taking omega as 0 and when omega is 0, K being minus omega square, next K equal to 0 and K equal to 0, we have already resolved, we found that it is inadmissible, so it was discarded. So, the case n equal to 0 is not possible, now when you take the negative integral values of n, because F x becomes here B sin omega x.

So, if you replace omega there, if you take n to be negative, because of sin minus theta equal to minus sin theta, the solutions will be just negative of the solution, that we get for positive integral values of n and so we may just consider a sufficient to the positive integral values of n. So, we may take n to be positive, because the negative values of n would give us the same solution except for a change of sign.

(Refer Slide Time: 15:55)

Thus $\omega = n\pi/l, n = 1, 2, 3, \dots$

Setting $B = 1$, we obtain infinitely many solutions $F(x) = F_n(x) = \sin (n \pi x / l), n=1,2,3, \dots$

Next,

$$\dot{T} - Kc^2 T = 0$$
$$\Rightarrow \dot{T} + c^2 \omega^2 T = 0$$

or

$$\dot{T} + \left(\frac{cn\pi}{l} \right)^2 T = 0$$

Thus, we may take ω as $n\pi$ over l , where n takes only positive integral values n equal to 1, 2, 3 and so on. we may set B equal to 1 for convenience, then we shall have infinitely many solutions of the differential equations of order 2, when F the solutions are $F(x)$ equal to $F_n(x)$ equal to $\sin n\pi x$ over l . For each value of n , we will get a solution of that differential equation, so we will have a sequence of solutions, we have denoted that by $F_n(x)$, $F_n(x)$ is then $\sin n\pi x$ over l , where n is taking values 1, 2, 3 and so on.

Now, having dissolved the second differential equation for F , now let us and found, we will now find the solution of the other differential equation, that is T dot minus Kc square T equal to 0. We have seen, while finding the solution of the differential equation for F , that K has to be taken minus ω square.

So, making use of K equal to minus ω square, this differential equation transforms into T dot plus c square ω square plus T equal to 0. Now, we have also noted that ω has to be taken equal to $n\pi$ over l . So, let us put the value of ω here, this differential equation, then a transforms into T dot plus $c n\pi$ over l whole square into T equal to 0, now for convenience $c n\pi$ over l , we are denoting by λ_n .

(Refer Slide Time: 17:35)

Setting $\lambda_n = cn\pi/l$, $n = 1, 2, \dots$ we have

$$\dot{T} + (\lambda_n)^2 T = 0$$

which implies that

$$T_n(t) = B_n \exp(-\lambda_n^2 t), \quad n = 1, 2, \dots$$

Thus,

$$u_n(x, t) = B_n \sin \frac{n\pi x}{l} \exp(-\lambda_n^2 t), \quad n = 1, 2, 3, \dots$$

are the solutions of the heat equation satisfying the boundary conditions.

So, let us say λ_n denotes $c n \pi$ over l , where n equal to 1, 2, 3 and so on. We may write the differential equation resulting differential equation as $T \dot{+} \lambda_n^2 T = 0$, which implies that, we can now separate the variables here. This $d T$ equal to minus λ_n^2 into T equal implies that $d T$ over T equal to minus λ_n^2 into $d T$.

We can then integrate on both Sides and we shall find that the solution general solution of this differential equation may written as $T_n t$ equal to B_n into e to the power minus λ_n^2 into t , n taking values 1, 2, 3 and so on, B_n s are arbitrary constants here, for each value of n . Now, let us substitute the value the solutions the values of $F x$ and $T t$ in $u x t$, so each value of n gives us one set of solutions for the two differential equations and therefore, it gives us a sequence of solutions $u_n x t$ of the heat equation.

So, here we will have $u_n x t$ equal to $B_n \sin n \pi x$ over l into exponential of minus λ_n^2 into t n taking values 1 2 3 and so on. So, these are the solutions of the heat equation, which satisfy the given boundary conditions, that is the ends of the bar are kept at temperature 0 throughout.

Now, since the heat equation δu over δt equal to c^2 $\delta^2 u$ over δx^2 is linear and homogeneous, just as in the case of the wave equation.

(Refer Slide Time: 19:32)

Since the heat equation is linear and homogeneous, superposing these solutions we have

$$u(x, t) = \sum_{n=1}^{\infty} B_n \sin\left(\frac{n\pi x}{l}\right) \exp\{-t\lambda_n^2\}.$$

Now, applying $u(x, 0) = f(x)$, we have

$$u(x, 0) = \sum_{n=1}^{\infty} B_n \sin\left(\frac{n\pi x}{l}\right) = f(x)$$

which is a half range expansion of $f(x)$.

Here, also we can superpose the solutions $u_n(x, t)$ and have the solution and have $u(x, t)$ as $\sum_{n=1}^{\infty} B_n \sin\left(\frac{n\pi x}{l}\right) \exp\{-t\lambda_n^2\}$. Now, let us apply the given initial condition, that is the initial temperature distribution in the bar is assume to be given by the function $F(x)$.

So, when you put t equal to 0 here, e to the power 0 is 1, so we shall have $u(x, 0)$ equal to $\sum_{n=1}^{\infty} B_n \sin\left(\frac{n\pi x}{l}\right)$, which is equal to the given function. Now, if you look at this equation $F(x) = \sum_{n=1}^{\infty} B_n \sin\left(\frac{n\pi x}{l}\right)$, you can see that it represents the half range expansion of the function $F(x)$.

(Refer Slide Time: 20:33)

Hence,

$$B_n = \frac{2}{l} \int_0^l f(x) \sin \frac{n\pi x}{l} dx.$$

Inserting this value of B_n in

$$u(x, t) = \sum_{n=1}^{\infty} B_n \sin \left(\frac{n\pi x}{l} \right) \exp \{-t\lambda_n^2\},$$

we get the required solution.

And therefore, B_n will be given by $\frac{2}{l} \int_0^l f(x) \sin \frac{n\pi x}{l} dx$, now let us insert this value of B_n in the series for $u(x, t)$, $u(x, t)$ is equal to $\sum_{n=1}^{\infty} B_n \sin \frac{n\pi x}{l} e^{-t\lambda_n^2}$. So, when you insert the value this value of B_n in this equation, you get the required solution.

(Refer Slide Time: 21:09)

It can be shown that the solution exists if $f(x)$ is piecewise continuous on the interval $0 < x < l$ and has one sided derivatives at all its interior points.

Now, it can be shown that the solution $u(x, t)$ exist, if $f(x)$ is piecewise continuous on the interval $0 < x < l$ and $f(x)$ has one sided derivatives at all its interior points.

(Refer Slide Time: 21:28)

Example. Find the temperature in a laterally insulated bar of length l whose ends are kept at 0°C , assuming that the initial temperature is

$$f(x) = \begin{cases} x & \text{if } 0 < x < l/2 \\ l-x & \text{if } l/2 < x < l. \end{cases}$$

Solution. The temperature is given by

$$u(x, t) = \sum_{n=1}^{\infty} B_n \sin\left(\frac{n\pi x}{l}\right) \exp\{-t\lambda_n^2\}.$$

Now, let us take an example on this problem, so let us find the temperature in a laterally insulated bar of length l , whose ends are kept at 0 degree centigrade, assuming that the initial temperature of the bar is given by the function $f(x)$ equal to x . If 0 is less than x less than $l/2$ and $l-x$, if $l/2$ is less than x less than l . We know that the temperature in the laterally insulated bar, uniform bar of length l is given by $u(x, t)$ equal to $\sum_{n=1}^{\infty} B_n \sin\left(\frac{n\pi x}{l}\right) \exp\{-t\lambda_n^2\}$.

If we assume that, the ends of the bar are kept at 0 temperature throughout and the initial temperature of the bar is assume to be $f(x)$. So, with that here $f(x)$ is given as x if 0 is less than x less than or by 2 and by $l-x$, if $l/2$ is less than x less than l , we shall be finding the value of B_n .

(Refer Slide Time: 22:43)

where

$$B_n = \frac{2}{l} \int_0^l f(x) \sin \frac{n\pi x}{l} dx.$$

$$= \frac{2}{l} \left(\int_0^{l/2} x \sin \frac{n\pi x}{l} dx + \int_{l/2}^l (l-x) \sin \frac{n\pi x}{l} dx \right)$$

$$= \begin{cases} 0, & \text{if } n \text{ is even,} \\ \frac{4l}{n^2 \pi^2}, & \text{if } n = 1, 5, 9, \dots \\ -\frac{4l}{n^2 \pi^2}, & \text{if } n = 3, 7, 11, \dots \end{cases}$$

So, B_n we know is given by $\frac{2}{l} \int_0^l f(x) \sin \frac{n\pi x}{l} dx$. Let us, put the values of $f(x)$ as x and $l-x$ over the interval 0 to l by $\frac{2}{l}$ and $\frac{2}{l}$ and then when you integrate by parts and simplify you can verify that B_n is equal to 0 . If n is an even integer and it is $\frac{4l}{n^2 \pi^2}$, if n takes value $1, 5, 9$ and so on. It is minus $\frac{4l}{n^2 \pi^2}$, if n takes values $3, 7, 11$ and so on.

(Refer Slide Time: 23:23)

Therefore the solution is given by

$$u(x,t)$$

$$= \frac{4l}{\pi^2} \left[\left(\sin \left(\frac{\pi x}{l} \right) \exp \left\{ -t \left(\frac{c\pi}{l} \right)^2 \right\} \right) \right.$$

$$\left. - \frac{1}{9} \left(\sin \left(\frac{3\pi x}{l} \right) \exp \left\{ -t \left(\frac{3c\pi}{l} \right)^2 \right\} \right) + \dots \right].$$

And, so let us put these values of B_n in the series for $u(x,t)$, we can see that $u(x,t)$ is equal to $\frac{4l}{\pi^2}$, which is common to all the terms multiplied by $\sin \frac{n\pi x}{l}$. So,

into exponential of minus $t c \pi$ over l whole square this the term corresponding to n equal to 1. Then, the term corresponding to n equal to 3 is this minus 1 over $9 \sin 3 \pi x$ over l exponential minus $t 3 c \pi$ over l whole square, this λ_n which is $c n \pi$ over l , so here n is 1, here n is 3.

(Refer Slide Time: 24:04)

Example. Find the temperature $u(x, t)$ in a bar whose ends are kept at temperature 0°C and whose initial temperature is $f(x) = x(10-x)$, taking $l = 10$ cm, cross section area = 1 cm^2 , density 10.6 gm/cm^3 , thermal conductivity = $1.04 \text{ cal/cm deg sec}$, and specific heat = 0.056 cal/gm deg .

Solution. Here

$$B_n = \frac{2}{10} \int_0^{10} x(10-x) \sin \frac{n\pi x}{10} dx, n = 1, 2, \dots$$

$$= 2 \int_0^{10} x \sin \frac{n\pi x}{10} dx - \frac{1}{5} \int_0^{10} x^2 \sin \frac{n\pi x}{10} dx$$

So, this was the problem where we had taken the two ends of the bar at 0 temperature, in this problem again, we take the ends at 0 temperature and but with a different function. Here, we have function $f(x)$ given by x into 10 minus x , we are given the specific values of l , the cross section area in form, l is assume to be 10 centimeter cross section area is assume to be 1 centimeter square density is given as 10.6 gram per centimeter cube thermal conductivity is this given a specific heat is given.

So, here straight away we shall find the value of the constants B_n , that occur in the infinite series for $u(x, t)$. So, we have B_n equal to 2 over 10 integral 0 to 10 x into 10 minus $x \sin n \pi x$ over 10 dx , where n takes value $1, 2, 3$ and so on.

Now, let us evaluate this integral, so we bracket into two parts and we then have B_n equal to 2 over 2 times integral 0 to 10 $x \sin n \pi x$ over 10 dx minus 1 over 5 integral 0 to 10 $x^2 \sin n \pi x$ over 10 dx . For convenience, let us call this first term on the right side as I_1 and the second term on the right side this one as I_2 .

(Refer Slide Time: 25:38)

$$\begin{aligned}
 &= I_1 - I_2 \text{ (say).} \\
 \text{Then} \\
 I_1 &= 2 \left[-\frac{10}{n\pi} \cos\left(\frac{n\pi x}{10}\right) \cdot x \right]_0^{10} + \frac{10}{n\pi} \int_0^{10} \cos\left(\frac{n\pi x}{10}\right) dx \\
 &= -\frac{200(-1)^n}{n\pi}. \\
 I_2 &= \frac{1}{5} \left[-\frac{10}{n\pi} \cos\left(\frac{n\pi x}{10}\right) \cdot x^2 \right]_0^{10} + \frac{20}{n\pi} \int_0^{10} x \cos\left(\frac{n\pi x}{10}\right) dx \\
 &= \frac{1}{5} \left[-\frac{1000}{n\pi} (-1)^n - \frac{200}{n^2 \pi^2} \left(-\frac{10}{n\pi} \cos\left(\frac{n\pi x}{10}\right) \right) \right]_0^{10}
 \end{aligned}$$

So, we write B_n as $I_1 - I_2$ and first we start the value at the integral I_1 using integration by parts, it comes out to be 2 times minus 10 over $n\pi$ cos $n\pi x$ over 10 into x , evaluated at 0 and 10 plus 10 over $n\pi$ integral 0 to 10 cos $n\pi x$ over 10 dx and when you substitute the lower and upper limits, you and simplify, you find that I_1 is equal to minus 200 into minus 1 to the power n over $n\pi$.

Again, we using integration by parts I_2 comes out to be $\frac{1}{5}$ into minus 10 over $n\pi$ cos $n\pi x$ over 10 into x^2 evaluated at 0 and 10 plus 10, 20 over $n\pi$ integral 0 to 10 $x \cos n\pi x$ over 10 dx . And when you put the lower and upper limits here and carry out the integral here and substitute the limits we have this.

(Refer Slide Time: 26:40)

$$\begin{aligned}
 &= \frac{1}{5} \left[-\frac{1000}{n\pi} (-1)^n + \frac{2000}{n^3\pi^3} ((-1)^n - 1) \right] \\
 &= -\frac{200}{n\pi} (-1)^n + \frac{400}{n^3\pi^3} ((-1)^n - 1).
 \end{aligned}$$

Hence

$$\begin{aligned}
 B_n &= -\frac{200}{n\pi} (-1)^n + \frac{200}{n\pi} (-1)^n - \frac{400}{n^3\pi^3} ((-1)^n - 1) \\
 &= \begin{cases} \frac{800}{n^3\pi^3} & \text{if } n \text{ is odd,} \\ 0 & \text{if } n \text{ is even.} \end{cases}
 \end{aligned}$$

Further, after simplification gives us 1 over 5 minus 1000 over n pi into minus 1 to the power n plus 2000 over n cube pi cube into minus 1 to the power n minus 1. And when we multiply by 1 over 5, it is n simplify further, I can we can write it as minus 200 over n pi minus 1 to the power n plus 400 over n cube pi cube into minus 1 to the power n minus 1. And hence B n is equal to I 1 minus I 2 gives us minus 200 over n pi minus 1 to the power n plus 200 over n pi minus 1 to the power n minus 400 over n cube, pi cube into minus 1 to the power n minus 1.

Now, if you take n to be a odd positive integer, then minus 1 to the power n minus 1 will become minus 2, so we shall have after simplification minus 1 to the power n be become minus 1. So, after simplification this will give us 800 over n cube pi cube because, when n is an odd integer this term and this term will cancel out. And this will give us minus 2s minus 2 into minus 1 mi plus 2, we have 800 over n cube pi cube and where n is even minus 1 to the power n becomes 1.

So, 1 minus 1 is 0, so this term becomes 0 and we get here 200 over n pi minus 200 over n pi which is again 0, so we get B n equal to 0, so when n takes values 2, 4, 6 and so on. We find that B n is 0 and when n takes values 1, 3, 5 and so on, we find that B n takes value 800 over n cube pi cube.

(Refer Slide Time: 28:38)

Now $\lambda_n = \frac{cn\pi}{l} = \sqrt{\frac{K}{s\rho}} \frac{n\pi}{l}$

Putting the values of K, s and ρ , we get

$$\lambda_n^2 = \frac{1.04}{0.056 \times 10.6} \frac{n^2 \pi^2}{100} = 0.01752 n^2 \pi^2.$$

Therefore,

$$u(x, t) = \sum_{n=1}^{\infty} B_n \sin\left(\frac{n\pi x}{l}\right) \exp\{-\lambda_n^2 t\},$$

$$= \frac{800}{\pi^3} \left[-\sin(0.1\pi x) \exp(-0.01752\pi^2 t) \right. \\ \left. + \frac{1}{27} \sin(0.3\pi x) \exp(-0.01752(3\pi)^2 t) + \dots \right]$$

Now, we have $c n$ equal to λ_n equal to $c n \pi$ over l and we know that c is equal to \sqrt{K} over s into ρ , because we had denoted k over $s \rho$ by c square. So, \sqrt{K} over $s \rho$, we have into $n \pi$ by l , l is 10 here. Now, let us put the values given values of K as $n \rho$ here and determine λ_n . In fact, if we write λ_n square, λ_n square comes out to be K that is 1.04 as $.056 \rho l$, 10.6 into n square π square over 100.

When, we evaluate the value of this, it is 1.04 over $.056$ into 10.6 into 1 by 100 , we come we get $.01752$ into and then n square π square. So, λ_n square is given as this value and therefore, $u(x, t)$ which is given by $\sum_{n=1}^{\infty} B_n \sin\left(\frac{n\pi x}{l}\right) \exp\{-\lambda_n^2 t\}$ is given by this series, 800 over π cube is common to all the terms we are taken it out.

And then, put the values of n , we have seen that, when n is an odd integer, it is having B_n is having value at 800 over n cube π cube. So, this is the term corresponding to n equal to 1, where we have made use of the value of λ_n square as this and this is the term corresponding to n equal to 3.

(Refer Slide Time: 30:21)

Bar with Non-zero End-temperatures

$$\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}, \quad \text{where } c^2 = \frac{K}{s\rho}.$$

and

$$u(0, t) = 0, \quad u(l, t) = u_0, \quad u(x, 0) = 0.$$

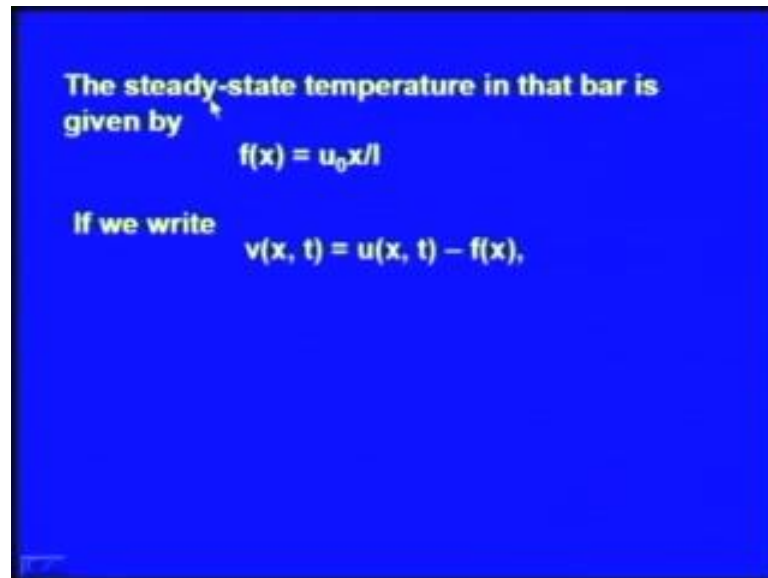

Since one of the boundary condition is not homogeneous, the method of separation of variables is not suitable.

Now, we discuss the case of the uniform bar, where the both the ends are not at 0 temperature, so let us take up the case of a bar with non 0 end temperature. So, here we have again have the same heat equation, $\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}$, where we had assumed that c^2 the diffusivity of the material is given by k over s rho.

We here assume that the end x equal to 0 is kept at 0 temperature throughout, while the end at the temperature x equal to l is maintained at u_0 and initially the temperature of the bar is 0. So, 1 end of the bar is kept at 0 temperature, the end of the other bar is raise to the temperature u_0 and is maintained their initially the bar was at 0 temperature.

Now, one of the boundary condition here that is the condition that at x equal to l , the end x equal to l is kept at 0 temp u_0 temperature and maintained throughout. The boundary condition is not homogeneous here, so the method of separation of variables cannot be is not suitable here.

(Refer Slide Time: 31:51)

The steady-state temperature in that bar is given by

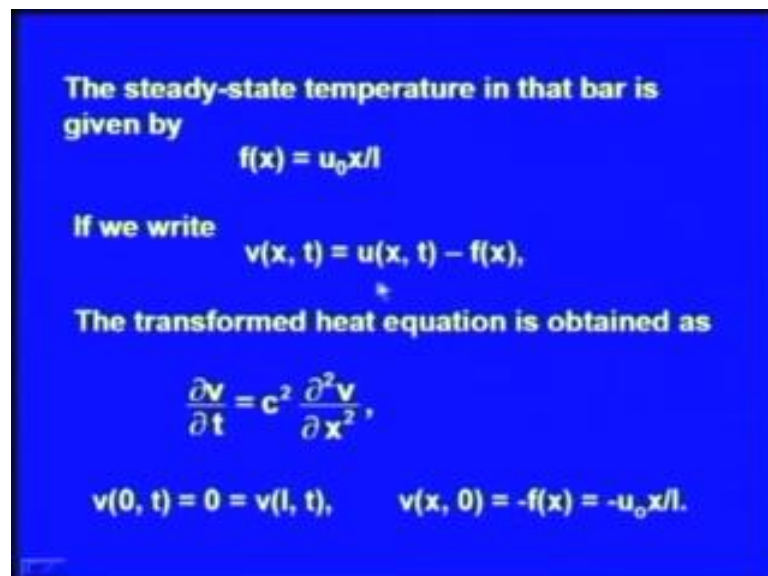

$$f(x) = u_0 x/l$$

If we write

$$v(x, t) = u(x, t) - f(x),$$

And therefore, what we will do is that, when the bar will come to the steady state, what happens is that the rate of change of u with respect to time is 0, that is $\frac{\partial u}{\partial t}$ is equal to 0. So, the heat equation becomes $\frac{\partial^2 u}{\partial x^2} = 0$ and therefore, $u(x, t)$ is the linear function of x only, $u(x, t)$ becomes $Ax + B$. And if, you put in that the initial condition the boundary condition that at $x = 0$, the u is 0 and at $x = l$ $u = u_0$, then what you get is $u(x, t)$ becomes $\frac{u_0 x}{l}$.

(Refer Slide Time: 32:35)

The steady-state temperature in that bar is given by

$$f(x) = u_0 x/l$$

If we write

$$v(x, t) = u(x, t) - f(x),$$

The transformed heat equation is obtained as

$$\frac{\partial v}{\partial t} = c^2 \frac{\partial^2 v}{\partial x^2},$$
$$v(0, t) = 0 = v(l, t), \quad v(x, 0) = -f(x) = -u_0 x/l.$$

So, that $u(x, t)$ we have written as $f(x)$, we write $v(x, t)$ as $u(x, t) - f(x)$, then the transformed heat equation is obtained as $\frac{\partial v}{\partial t} = c^2 \frac{\partial^2 v}{\partial x^2}$. Because, $\frac{\partial v}{\partial t}$ gives you $\frac{\partial u}{\partial t}$, the partial derivative of $f(x)$ with respect to t is 0.

So, $\frac{\partial v}{\partial t}$ is equal to $\frac{\partial u}{\partial t}$ and when you differentiate v with respect to x partially twice, that is $\frac{\partial^2 v}{\partial x^2}$, you find then you get $\frac{\partial^2 u}{\partial x^2} - \frac{\partial^2 f(x)}{\partial x^2}$. But, $f(x)$ being a linear function of x , that is $u_0 \frac{x}{l}$, when you differentiate $f(x)$ twice with respect to x , it will give you 0.

So, $\frac{\partial^2 v}{\partial x^2}$ is same as $\frac{\partial^2 u}{\partial x^2}$ and therefore, the heat equation which we had assumed as $\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}$ is transformed into $\frac{\partial v}{\partial t} = c^2 \frac{\partial^2 v}{\partial x^2}$. The bound the boundary conditions which we had assumed as $u(0, t) = 0$ and $u(l, t) = u_0$ transformed into $v(0, t) = 0$, because when you put $x = 0$ here $v(0, t)$ becomes $u(0, t) - f(x)$.

So, and $v(l, t)$ is equal to when you put $x = l$ here, we get $v(l, t) = u(l, t) - f(x)$, $u(l, t)$ is assumed to be u_0 and then, here when you put $x = l$, $f(x)$ also is equal to u_0 . So, $u_0 - u_0$ is 0, so we get $v(l, t) = 0$.

So, the two boundary conditions for u are transformed into $v(0, t) = 0$ and $v(l, t) = 0$, the initial condition for u , we had assumed as $u(x, 0) = 0$. So, the initial condition, you had assumed as $u(x, 0) = 0$, we had started with initial temperature being 0. So, here $v(x, t)$, when you put $t = 0$ we get $v(x, 0) = u(x, 0) - f(x)$. So, that is we get $v(x, 0) = -f(x)$, but $f(x)$ is $u_0 \frac{x}{l}$, so we get $v(x, 0) = -u_0 \frac{x}{l}$. So, now we transformed equation, which is again the equation of heat conduction type, we have the two end temperatures as zeros and the initial temperature distribution is given by a function of x minus $u_0 \frac{x}{l}$.

(Refer Slide Time: 35:55)

The solution is therefore

$$v(x, t) = \sum_{n=1}^{\infty} B_n \sin\left(\frac{n\pi x}{l}\right) \exp\{-t\lambda_n^2\}, \lambda_n = \frac{cn\pi}{l},$$

where

$$B_n = \frac{2}{l} \int_0^l f(x) \sin\frac{n\pi x}{l} dx.$$

$$= \frac{2}{l} \int_0^l \left(-\frac{u_0 x}{l}\right) \sin\frac{n\pi x}{l} dx$$

$$= \frac{2u_0(-1)^n}{n\pi}.$$

Hence the solution is given by

Such a case, we have already solved and we have seen that the solution is comes out to be $v \times t$ equal to sigma n equal to 1 to infinity, $B_n \sin \frac{n\pi x}{l}$ into exponential of minus t lambda n square, where lambda n is $c n \pi$ over l . And we know that the values of B_n 's are given by $\frac{2}{l}$, integral 0 to l $f(x) \sin \frac{n\pi x}{l}$. So, here $f(x)$ is minus $u_0 x$ over l and therefore, B_n is $\frac{2}{l}$, 0 to l minus $u_0 x$ over l into $\sin \frac{n\pi x}{l}$ over l dx . When, you integrate this function and put the limits, what you get is B_n equal to $\frac{2}{l}$ into u_0 minus 1 to the power n over $n \pi$.

(Refer Slide Time: 36:44)

$$u(x, t) = \frac{u_0 x}{l} + \sum_{n=1}^{\infty} \frac{2u_0(-1)^n}{n\pi} \sin\left(\frac{n\pi x}{l}\right) \exp\{-t\lambda_n^2\}.$$

Let the temperature of the end $x=0$ be raised suddenly to T_0 while that of the end $x=l$ be reduced to T_1 and kept so. The final distribution, in the steady state is

$$u = T_0 + \frac{T_1 - T_0}{l} x.$$

Hence, the solution is given by now $v(x, t)$ is equal to $u(x, t)$ minus $u_{\text{naught}} x$ over l , because we had defined $v(x, t)$ as $u(x, t)$ minus $f(x)$ and $f(x)$ had come out to be $u_{\text{naught}} x$ over l . So, $v(x, t)$, we found as being equal to $u(x, t)$ minus $u_{\text{naught}} x$ over l , so let us put the value of $v(x, t)$ here and then take the term $u_{\text{naught}} x$ over l to the other side. We have $u(x, t)$ equal to $u_{\text{naught}} x$ over l plus sigma n equal to 1 to infinity, they may there is the value of B_n^2 into $u_{\text{naught}} \text{minus } 1$ to the power n over $n \pi$ into $\sin n \pi x$ over l into exponential of minus $t \text{ lambda } n^2$.

Now, let us take the range the end, temperature of the end x equal to 0 suddenly to T_{naught} and while the temperature of the end x equal to l be reduced to T_1 and kept so throughout. Then, when the bar comes back to be steady state, the final distribution in distribution of temperature will be given by u equal to T_{naught} plus T_1 minus T_{naught} over l into x , because again when the bar comes back to the steady state, you will be equal to a linear function of x .

So, you we you will be equal to $A x$ plus B and when you will find the values of the constants A and B making use of these conditions that at x equal to 0, the temperature u is T_{naught} and x equal to l , the temperature u is T_1 . Then, we will get the values of A and B , A will be equal to T_{naught} , A plus $B x$, if you write u equal to A plus $B x$, then A will be equal to T_{naught} B will come out to be T_1 minus T_{naught} over l . So, u is equal to T_{naught} plus T_1 minus T_{naught} over l into x .

(Refer Slide Time: 38:47)

$$u(x, t) = T_0 + \frac{T_1 - T_0}{l} x + \sum_{n=1}^{\infty} B_n^* \sin\left(\frac{n\pi x}{l}\right) \exp\{-t \lambda_n^2\}. \quad (1)$$

Applying the initial condition $u = u_0 x/l$, when $t = 0$, we have

$$\frac{u_0 + T_0 - T_1}{l} x - T_0 = \sum_{n=1}^{\infty} B_n^* \sin\left(\frac{n\pi x}{l}\right).$$

Therefore

$$B_n^* = \frac{2}{l} \int_0^l \left\{ \frac{u_0 + T_0 - T_1}{l} x - T_0 \right\} \sin \frac{n\pi x}{l} dx.$$

Substituting the value of B_n^* in (1) gives the solution.

And then, the solution will take the form $u(x,t) = T_1 + (T_2 - T_1) \frac{x}{l} + \sum_{n=1}^{\infty} B_n \sin \frac{n\pi x}{l} e^{-\lambda_n^2 t}$, where we have applied the initial condition, that u is equal to $u_0(x)$. Initially, we have started here, counting the time, we are from the stage, when the initial temperature distribution in the bar was given by $u = u_0(x)$.

Now, let us put $t = 0$ here, when you put $t = 0$ here $u(x,0) = u_0(x)$ and this u to the power e to the power 0 becomes 1 here. So, let us evaluate the values of the constants B_n here, the this equation trans implies the gives us $u_0(x) = T_1 + (T_2 - T_1) \frac{x}{l} + \sum_{n=1}^{\infty} B_n \sin \frac{n\pi x}{l}$. When, you make use of this initial condition, that is at $t = 0$, $u(x,t) = u_0(x)$.

So, then again half range expansion for this function, so the value of B_n , we can write the B_n will be $\frac{2}{l} \int_0^l u_0(x) \sin \frac{n\pi x}{l} dx$. So, $u_0(x) = T_1 + (T_2 - T_1) \frac{x}{l} + \sum_{n=1}^{\infty} B_n \sin \frac{n\pi x}{l}$, now when you evaluate the value of this B_n and substitute, it in this equation 1, you get the temperature distribution in the bar $u(x,t)$.

(Refer Slide Time: 40:51)

Example. An insulated rod of length l has its ends A and B maintained at 0°C and 100°C respectively until steady state prevails. If B is suddenly reduced to 0°C and maintained at 0°C , find the temperature at a distance x from A at time t .

Solution.

The governing one dimensional heat equation is

$$\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}.$$

Let us take an example on this problem on this article an insulated rod of length l has its ends A and B maintained at 0 degree centigrade and 10 degree centigrade respectively.

Until a steady state conditions prevail, if B suddenly reduce to 0 degree centigrade and maintained at 0 degree centigrade, find the temperature at a distance x from A at time t.

So, here we have a problem where the end A is kept at 0 degree centigrade, the end B is kept at 100 degree centigrade. So, here u naught is equal to 100 degree centigrade, until a steady state conditions prevail. So, when this bar comes back to the steady state suddenly what is done is the end B is cooled to 0 degree centigrade. When, the end B is cooled 0 degree centigrade a fresh flow of heat takes place in the bar and before it comes back to the a steady state. We have to find the temperature at a distance x and from the end A at time t in the intermediate stage, that is in the transient stage. Now, we know that the governing one dimensional heat equation, we know it is Δu over Δt equal to c square.

(Refer Slide Time: 42:19)

Here the initial condition is $u(x,0) = \frac{100}{l}x$,
and its solution is given by

$$u(x,t) = \sum_{n=1}^{\infty} B_n \sin\left(\frac{n\pi x}{l}\right) \exp\left\{-t\left(\frac{cn\pi}{l}\right)^2\right\}.$$

$\Delta^2 u$ over Δx^2 and initial condition here is that $u(x,0)$ is u naught x by l , we have seen that u naught is 100 here. So, $u(x,0)$ is equal to $100x$ by l and its solution is given by $u(x,t)$ equal to $\sum_{n=1}^{\infty} B_n \sin\left(\frac{n\pi x}{l}\right) \exp\left\{-t\left(\frac{cn\pi}{l}\right)^2\right\}$. Because, here we have the end x equal to 0 is kept at temperature 0 and where the end B is cooled to temperature 0 . So, here T_0 is 0 and T_l is also 0 , so if you put these values of T_0 and T_l in the article and then, you can see that a $u(x,t)$ becomes this infinite series.

(Refer Slide Time: 43:13)

Here the initial condition is $u(x,0) = \frac{100}{l}x$,
and its solution is given by

$$u(x,t) = \sum_{n=1}^{\infty} B_n^* \sin\left(\frac{n\pi x}{l}\right) \exp\left\{-t\left(\frac{cn\pi}{l}\right)^2\right\}.$$

Putting $t = 0$ and using $u(x,0) = \frac{100}{l}x$, we get

$$\frac{100}{l}x = \sum_{n=1}^{\infty} B_n^* \sin\left(\frac{n\pi x}{l}\right)$$

Where, when you put t equal to 0, you get $u = \frac{100}{l}x$ by 1 equal to $\sum_{n=1}^{\infty} B_n^* \sin\left(\frac{n\pi x}{l}\right)$.

(Refer Slide Time: 43:31)

Then

$$B_n^* = \frac{2}{l} \int_0^l \frac{100}{l}x \sin\frac{n\pi x}{l} dx.$$
$$= \frac{200}{l^2} \left[x \left\{ -\frac{\cos(n\pi x/l)}{(n\pi/l)} \right\} + \left\{ \frac{\sin(n\pi x/l)}{(n\pi/l)^2} \right\} \right]_0^l$$
$$= \frac{200}{n\pi} (-1)^{n+1}.$$

Therefore the solution is

$$u(x,t) = \frac{200}{\pi} \sum_{n=1}^{\infty} \frac{(-1)^{n+1}}{n} \sin\left(\frac{n\pi x}{l}\right) \exp\left\{-t\left(\frac{cn\pi}{l}\right)^2\right\}.$$

So, the values of B_n^* , we can find B_n^* will be $\frac{2}{l} \int_0^l \frac{100}{l}x \sin\frac{n\pi x}{l} dx$ and when you integrate this by parts. And then, you get $\frac{200}{l^2}$ multiplied by x into $-\frac{\cos n\pi x}{n\pi}$ by 1 plus $\frac{\sin n\pi x}{n\pi}$ by 1 whole square evaluated at 0 and l .

And, when you put these values that the lower and upper limits and simplify the values of B_n are given by $\frac{200}{n\pi} \sin n\pi x$ where n takes values 1, 2, 3 and so on. So, let us substitute those values of B_n in this infinite series for u we get $u(x, t) = \frac{200}{\pi} \sum_{n=1}^{\infty} \frac{1}{n} \sin n\pi x \exp(-c^2 n^2 \pi^2 t)$.

(Refer Slide Time: 44:41)

Example. A bar with insulated sides is initially at temperature 0°C throughout. The end $x = 0$ is kept at 0°C , and heat is suddenly applied at the end $x = l$ so that $\frac{\partial u}{\partial x} = A$ for $x = l$, where A is a constant. Find the temperature function $u(x, t)$.

Solution. For the heat equation

we have
$$\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2},$$

$$u = (A \cos \omega x + B \sin \omega x) \exp(-c^2 \omega^2 t) \quad (2)$$

Now, let us take another problem, where we are given different boundary conditions, then the boundary conditions that we are discussed so far, a bar with insulated sides is initially at temperature 0 degree centigrade throughout. So, we are assuming here that $u(0, t) = 0$ for all t and the end $x = l$ is kept at 0 degree centigrade and heat is suddenly applied at the $x = l$. So, that $\frac{\partial u}{\partial x} = A$ for all t at $x = l$.

So, the gradient is kept at a constant A for at the end $x = l$, where A is a constant we have to determine the temperature function $u(x, t)$ here. Now, so let us see how do we solve such a problem, where the boundary conditions are not the as we have taken in the case of the article here. We are taking, we are given the gradient instead of the value of u at $x = l$, so how will do such a problem.

Now, we have seen that when you solve this partial differential equation $\frac{\partial u}{\partial t} = c^2 \frac{\partial^2 u}{\partial x^2}$, what you do is you write u as $f(x) \exp(-c^2 \omega^2 t)$.

T t. And then, you discuss the cases K equal to 0, K greater than 0, K less than 0, what you do note is that K less than, K equal to 0 and K greater than 0 are to be discarded.

We have to take K negative and when you take k equal to minus 1 omega square, you get u x t equal to A cos omega x plus B sin omega x into exponential minus c square omega square into t. We have to find the values of A and B making use of the given boundary conditions here.

(Refer Slide Time: 46:44)

Imposing on (2) the zero end conditions:
 $u = 0$ at $x = 0$; $\partial u / \partial x = 0$ at $x = l$,
 we have $A = 0$ and $\cos \omega l = 0$ i.e.
 $\omega l = (2n - 1) \frac{\pi}{2}$, $n = 1, 2, \dots$

So, what we will do as we have done in the case of finding temperature for a bar with non 0 end temperatures. We hear what are all will be do is that we start with 0 and conditions, we assume that at x equal to 0 u is 0, which is given to us at the end x equal to 0 the temperature gradient is 0. We first at assume that, the temperature gradient at the end x equal to 0 is also 0 and then we shall take the case where the temperature at the end x equal to l will be taken as A.

So, u x t equal to A cos omega x plus B sin omega x into e to the power minus c square omega square into t, implies that A is equal to 0, which follows, when you take a u to be 0 at x equal to 0. And also cos omega l equal to 0, which follows, when you take the partial derivative of u with respect to l and u is the condition that delta u over delta x is 0 at x equal to l at for all the time t.

Now, $\cos \omega l = 0$ gives you $\omega l = (2n - 1)\pi/2$, where n takes value 1, 2, 3 and so on, here again as we have done in the previous case as the bar with 0 end temperatures, that here we have to take the only positive integral values of n . When, you take the negative integral value of n , you only get the solutions which are the negative of the solutions for the positive integral values of n .

(Refer Slide Time: 48:27)

Imposing on (2) the zero end conditions:

$u = 0$ at $x = 0$; $\partial u / \partial x = 0$ at $x = l$,
we have $A = 0$ and $\cos \omega l = 0$ i.e.

$$\omega l = (2n - 1)\frac{\pi}{2}, \quad n = 1, 2, \dots$$

Hence

$$u(x, t) = \sum_{n=1}^{\infty} B_n \sin \omega x \exp \{-\omega^2 t\},$$

where $\omega = (2n - 1)\frac{\pi}{2l}$.

So, we will get $u(x, t) = \sum_{n=1}^{\infty} B_n \sin \omega x \exp \{-\omega^2 t\}$, where $\omega = (2n - 1)\pi/2l$.

(Refer Slide Time: 48:41)

Let us define a function

$$v(x, t) = u(x, t) - Ax.$$

Then the heat equation is transformed into

$$\frac{\partial v}{\partial t} = c^2 \frac{\partial^2 v}{\partial x^2},$$

and the boundary conditions become

$$v = 0 \text{ at } x = 0 \text{ and } \frac{\partial v}{\partial x} = 0 \text{ at } x = l.$$

So we may write

$$v(x, t) = \sum_{n=1}^{\infty} B_n \sin \omega_n x \exp\{-\omega_n^2 t\},$$

Now, let us define a function $v(x, t)$ equal to $u(x, t) - Ax$, in a similar way as we had define for the case, where we are taken bar with non 0 end temperatures to reduce the problem to a bar with 0 end temperatures. So, here we again define a function $v(x, t)$ equal to $u(x, t) - Ax$ and then the heat equation as we had done in the case of the bar with 0 and non 0 end temperatures, the heat equation is transformed into $\frac{\partial v}{\partial t} = c^2 \frac{\partial^2 v}{\partial x^2}$.

So, the boundary conditions reduce or you can say the boundary conditions change into when we have assume that at t equal to 0, $u(x, 0)$ is equal to 0, so here also, when you put t equal to 0, $v(x, 0)$ comes out to be 0 minus 0, so v is equal to 0 at x equal to 0. We have assume that at x equal to 1, $\frac{\partial u}{\partial x}$ is equal to A , it is given to us, so $\frac{\partial v}{\partial x}$, if you write $\frac{\partial v}{\partial x}$, will be $\frac{\partial u}{\partial x} - A$. And when you put $\frac{\partial u}{\partial x}$ as A , then you get $\frac{\partial v}{\partial x}$ as equal to 0 at x equal to 1.

So, the problem now reduces to the problem, which we have are already just now done that, where we had to set that at x equal to 0, the temperature is 0 and at x equal to 1, the temp the temperature gradient is 0. So, while defining this function $v(x, t)$, we reduce the problem, where at the end is equal to 0, the temperature gradient is given to be a constant A to the problem, where the temperature gradient at the end x equal to 1 is also 0.

So, with this at a transformation we will have the solution of the heat equation, $\frac{\partial v}{\partial t}$ or this equation $\frac{\partial v}{\partial t} = c^2 \frac{\partial^2 v}{\partial x^2}$ as $v(x, t) = \sum_{n=1}^{\infty} B_n \sin \omega_n x \exp\{-\omega_n^2 t\}$.

(Refer Slide Time: 51:07)

$$u(x, t) = Ax + \sum_{n=1}^{\infty} B_n \sin \omega_n x \exp\{-\omega_n^2 t\},$$
 where $\omega_n = (2n-1)\frac{\pi}{2l}$.
 Using the initial condition $u = 0$ at $t = 0$, we get

$$0 = Ax + \sum_{n=1}^{\infty} B_n \sin \omega_n x$$
 or

$$-Ax = \sum_{n=1}^{\infty} B_n \sin \omega_n x.$$
 Therefore

Let us replace the value of $v(x, t)$, $v(x, t)$ is equal to $u(x, t) - Ax$, so $u(x, t)$ will be equal to $Ax + \sum_{n=1}^{\infty} B_n \sin \omega_n x \exp\{-\omega_n^2 t\}$; where ω_n , we know is equal to $(2n-1)\frac{\pi}{2l}$ or we can say ω_n is equal to $(2n-1)\frac{\pi}{2l}$ and taking positive integral values.

Now, let us make use of the initial condition that is at t equal to 0, the initial temperature distribution in the bar is 0. So, when you make use of that, we will get 0 equal to $Ax + \sum_{n=1}^{\infty} B_n \sin \omega_n x$ or we can say that $\sum_{n=1}^{\infty} B_n \sin \omega_n x$ will be equal to $-Ax$. So, we shall get half range expansion of the function $-Ax$.

So, this is what we get, 0 equal to $Ax + \sum_{n=1}^{\infty} B_n \sin \omega_n x$ and then or we may write this equation as $-Ax = \sum_{n=1}^{\infty} B_n \sin \omega_n x$.

$$\begin{aligned}
 B_n^* &= \frac{2}{l} \int_0^l (-Ax) \sin \omega x \, dx. \\
 &= \frac{2}{l} \left[(-Ax) \left(-\frac{1}{\omega} \cos \omega x \right) - (-A) \left(-\frac{1}{\omega^2} \sin \omega x \right) \right]_0^l \\
 &= \frac{2A}{l\omega} \left[\omega \cos \omega l - \frac{1}{\omega} \sin \omega l \right] \\
 &= \frac{2Al \cdot 2^2}{(2n-1)^2 \pi^2} \sin \left(n\pi - \frac{\pi}{2} \right) \\
 &= \frac{8Al \cdot (-1)^n}{(2n-1)^2 \pi^2}
 \end{aligned}$$

Therefore, B_n^* will be given by $\frac{2}{l} \int_0^l (-Ax) \sin \omega x \, dx$ and we can then evaluate the value of this integral by using integration by parts. It will come out to be $\frac{2}{l} \left[(-Ax) \left(-\frac{1}{\omega} \cos \omega x \right) - (-A) \left(-\frac{1}{\omega^2} \sin \omega x \right) \right]_0^l$, which is the integral of $\sin \omega x$ minus derivative of $-Ax$, which is $-A$ into integral of this function, that is $-\frac{1}{\omega^2} \sin \omega x$ evaluated at 0 and l .

So, this when you put the lower and upper limits 0 and l , we will get $\frac{2A}{l\omega} \left[\omega \cos \omega l - \frac{1}{\omega} \sin \omega l \right]$ and we simplified further use ω equal to $\frac{2n-1}{2l} \pi$. So, we get it as $\frac{2Al \cdot 2^2}{(2n-1)^2 \pi^2} \sin \left(n\pi - \frac{\pi}{2} \right)$. And when you evaluate the value of $\sin \left(n\pi - \frac{\pi}{2} \right)$, you get this value of B_n^* as $\frac{8Al \cdot (-1)^n}{(2n-1)^2 \pi^2}$.

(Refer Slide Time: 53:48)

Hence the solution of the given problem is

$$u(x, t) = Ax + \frac{8A}{\pi^2} \sum_{n=1}^{\infty} \frac{(-1)^n}{(2n-1)^2} \sin \omega x \exp\{-\omega^2 t\},$$

where $\omega = (2n-1)\frac{\pi}{2l}$.

And thus, we can write the solution of the given problem $u(x, t)$ equal to Ax plus $\frac{8A}{\pi^2}$ into sigma n equal to 1 to infinity minus 1 to the power n over $(2n-1)^2$ into sin ωx into exponential minus $\omega^2 t$; where ω is equal to $(2n-1)\frac{\pi}{2l}$.

Thus, we have solved the one dimensional wave equation and the one dimensional heat equation using the method of separation of variables. We can also discuss two dimensional wave equation and the two dimensional heat equation or even three dimensional heat equation using the method of separation of variables. So, the two dimensional cases will be covered in the next in the other lectures, where we will be discussing the rectangular region. In the case of a two dimensional wave equation and a rectangular plate for two dimensional heat equation and we shall solve them using the product method, that is the method of separation of variables in a similar fashion.

Thank you.
