**Lecture - 14**  
**Fourier Integrals**

Welcome to the lecture series on differential equations for under graduate students. Today's lecture is on Fourier Integrals. In some last lectures we had seen that Fourier series are very important tool in solving many practical problems involving, periodic functions. Let us try to extend this idea, to non periodic function as well, because in many practical problems, we have functions which are not periodic. So, let us try it, to extend this, in this one and let us first see with the help of example.

(Refer Slide Time: 01:10)

**Example**

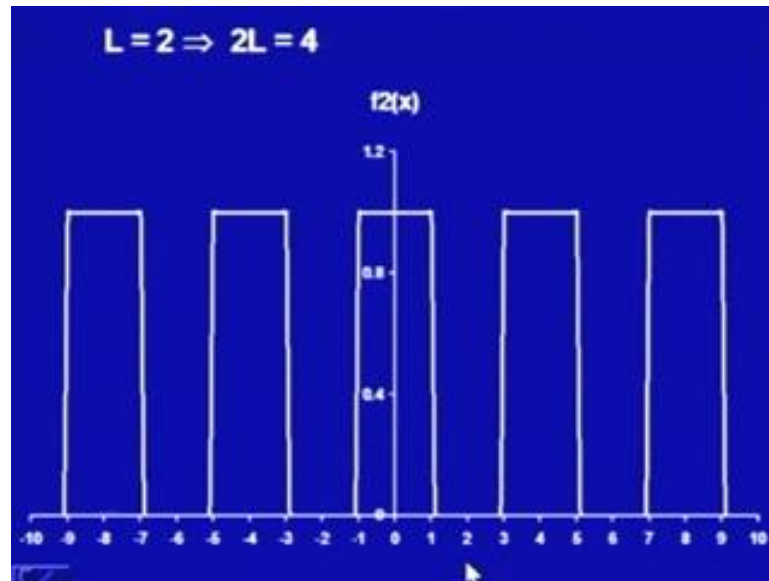

Consider the periodic square wave have  $f_L(x)$  of period  $2L > 2$  as

$$f_L(x) = \begin{cases} 0 & -L < x < -1 \\ 1 & -1 < x < 1 \\ 0 & 1 < x < L \end{cases}$$

$f_L(x+2L) = f_L(x)$

Consider the periodic square wave  $f_L(x)$  as 0 from minus  $L$  to minus 1, 1 from minus 1 to 1 and 0 from 1 to  $L$ . So, certainly we want that, this period  $2L$  has to be greater than, 2 since we want from minus 1 to plus 1 it should be 1, and after that it should be 0, and we want it is periodic with period  $2L$ , so  $f_L(x+2L)$  should be equal to  $f_L(x)$  for all  $x$ .

(Refer Slide Time: 01:42)

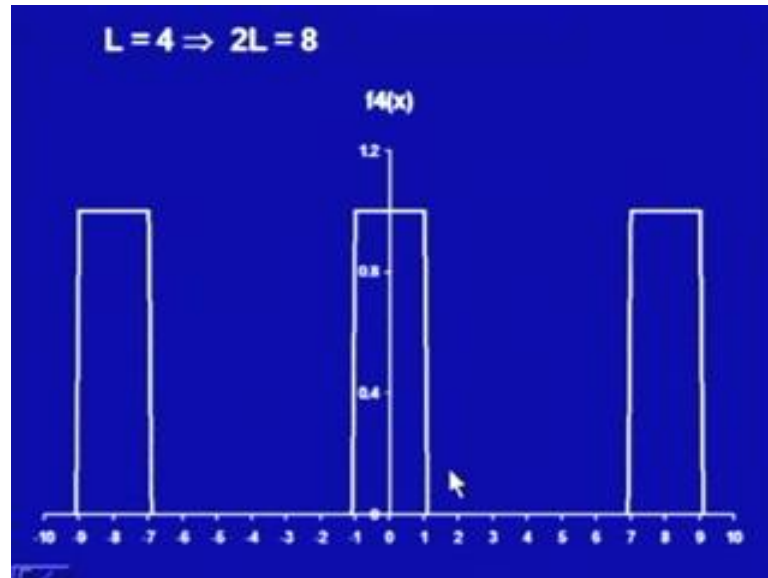

Let us see, how this function looks like, why we are calling a square wave, so if I take,  $L$  is equal to 2 that means, period  $2L$  would be 4, and the function would be, 0 from minus 2 to minus 1, then 1 from minus 1 to plus 1, and then again 0 from 1 to 2. And we are making it periodic from  $f(x+4) = f(x)$ , that is, we are just moving here, after that here from minus 2 to plus 2, and then again we are repeating, so whatever the function over here, were repeating like this, so here, we are getting is this square waves.

(Refer Slide Time: 02:22)

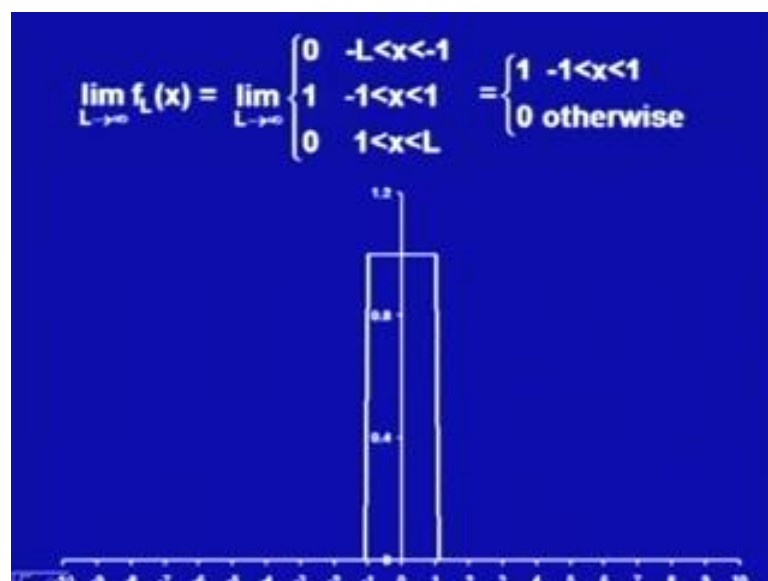

Now, if I extend this  $L = 2, 3$ , we would get, again that from minus 3 to minus 1, 0, 1 to plus 1 it will be plus 1, and then 1, 2, 3 it is 0, again, now the period is 6. So, we would repeat it after that 1, so we are getting, the squares a little further.

(Refer Slide Time: 02:41)

Again if I take,  $L$  is equal to 4, it would be like this, so if I move 1 like this, we would be getting is that these squares, would be recurring, at a more and more distances, let us see, if I take  $L$  to be very large.

(Refer Slide Time: 02:57)

That is take the limit as, L approaches to infinity of this function, that says is, I would get the function 1, in minus 1 to plus 1, and 0 otherwise, because L we are approaching to the infinity, so from minus infinity to minus 1 it would be 0, and from 1 to infinity it would be 0. What this function would look like, 1 square in between, from minus 1 to plus 1, and 0 elsewhere, now let us see, this we have said is that is,  $f_L(x)$  is a periodic function. Now, let us see, how this Fourier series of this function,  $f_L(x)$  will behave, when we increase, L or we change the L.

(Refer Slide Time: 03:40)

**Fourier series (or co-efficient)**

$$f_L(x) = \begin{cases} 0 & -L < x < -1 \\ 1 & -1 < x < 1 \\ 0 & 1 < x < L \end{cases} \quad f_L(x+2L) = f_L(x)$$

$$a_{0,L} = \frac{1}{2L} \int_{-1}^1 dx = \frac{1}{L}$$

$$a_{n,L} = \frac{1}{L} \int_{-1}^1 \cos \frac{n\pi x}{L} dx = \frac{2}{L} \int_0^1 \cos \frac{n\pi x}{L} dx$$

and

$$b_{n,L} = \frac{1}{L} \int_{-1}^1 \sin \left( \frac{n\pi x}{L} \right) dx = 0$$

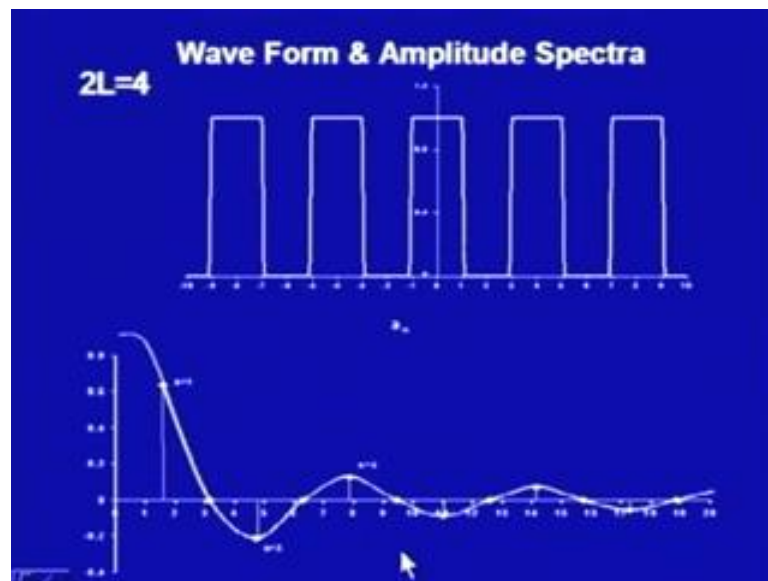

$$|a_{n,L}| = \frac{2}{n\pi} \left| \sin \left( \frac{n\pi}{L} \right) \right|$$

So, let us see first, for the Fourier series for  $f_L(x)$ , this is  $f_L(x)$ , which is, 1 in minus 1 to plus 1, and 0 from minus L to plus minus 1 and 0, from 1 to L and then periodic, with  $f_L(x)$  plus 2L as  $f_L(x)$ , find out what is the Fourier coefficients, that is using the Euler's formula,  $a_{n,L}$ ,  $L$  I am using, that is we are using this, particular L. One upon 2L minus 1 to plus 1 dx, because the function is 0 from minus L to minus 1 and 0, from 1 to L so we do have 1 only in the interval minus 1 to plus 1, which is nothing but 1 by L.

And what will be  $a_n$ ,  $a_n$  would be nothing but 1 upon L, integral minus 1 to plus 1 cos n pi x by L dx, because the function  $f_L(x)$  is 1 in the interval minus 1 to plus 1. What will be it is this integral ((Refer Time: 04:34)) function, we can write as two times, so 2 by L 0 to 1 cos n pi x over L dx, it is integral is nothing but the sine n pi x by L divided by n pi by L, evaluated from 0 to 1, we would get finally as, 2 by L sine n pi by L upon sine n pi L.

Now, what will be the coefficient  $b_n$ ,  $b_n L$  would be,  $\int_{-L}^L 1 \sin n \pi x / L dx$ , now you see this function is, odd function in this one, so this should be integral should be 0. So, we are getting finally, Fourier cos series for this function, and what will be it is amplitude, because  $b_n$  is 0, we would get the modulus of  $a_n$  that is, square root of the,  $a_n^2 + b_n^2$  an square  $b_n$  is 0, so  $a_n^2$  only square root we do take only positive quantity. So, it would be  $2 \sin n \pi$  by  $L$ , now if I, just plot this one, this is called the Fourier amplitude spectrum.

(Refer Slide Time: 05:44)

Let us see, this curve, first we have taken that  $2L$  is 4, so the wave forms are, a closer enough, this kind of function we were having, if I plots it is amplitude spectra that means, I am plotting,  $a_n L$  versus  $n \pi L$ ,  $a_n L$  was,  $2 \sin n \pi$  modulus of  $\sin n \pi$  by  $L$ . Now, when  $L$  is equal to here 2, so what we would be having is  $2 \sin n \pi$  by 2, now when  $n$  is 1  $\sin \pi$  by 2 is 1, what I would get, amplitude as 2 upon  $\pi$ , and here we are plotting it with,  $n \pi$  by  $L$  that is here  $n$  is 1, that is  $\pi$  by 2 at  $\pi$  by 2 I am plotting it here.

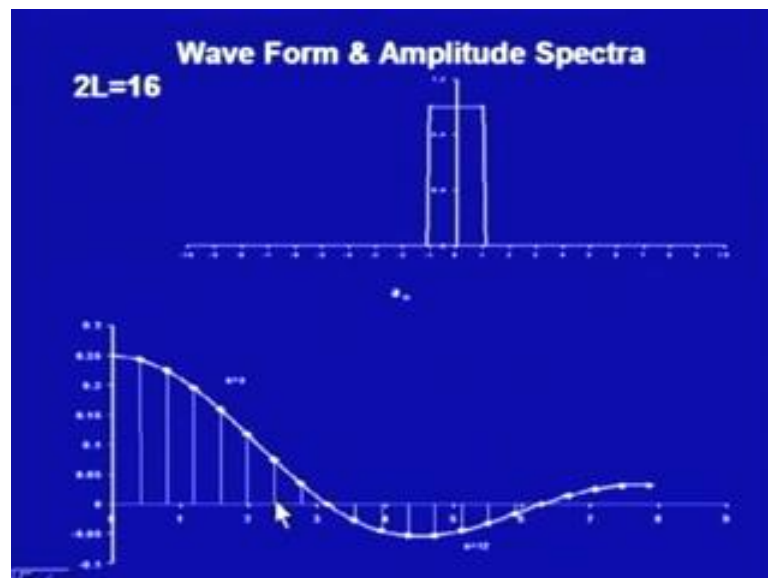

Like this, this is been plotted, so when  $n$  is equal to 3 I would be more less 1 and like that, now we see, in this graph, we are getting this wave, then it is going down, then it is coming up. So, we call it half wave, in each half wave I am having 1 maximum amplitude.

(Refer Slide Time: 07:01)

Let us see, when  $L$  is equal to 4, that is my period is now 8, this be the function type, now if I am plotting this, the maximum value, which we would be going for  $n$  is equal to, 2 here. That, would be here, because  $n$  is equal to 1, we would be taking it  $\pi$  by 4, like that, we just come here, this is value is less than your 0.5, in the first one it was less than 0.8. Now, here it is less than 0.5, and in half wave I am having, 3 amplitudes for each one, like that we are going on.

(Refer Slide Time: 07:46)

Now, if I take  $L$  is equal to 16 of course, here next one has not been plotted, it would be little bit far away, we do get, these kind of one, and maximum value we are getting is less than 0.25. Now, what we are seeing in all these graphs, where I am plotting this amplitude versus, this  $\omega$  and we would call  $n\pi$  by  $L$  as  $\omega_n$ , we are getting is, that as we are increasing my  $L$ , our amplitudes are, coming more and more in half wave, that is they are becoming dense.

Moreover, their value or this length is decreasing, so what we say is that, if I increase my  $L$ , I would get that, this will become more dense, having half wave many of them, and the length, that will decrease and you could reach to the 0. What now, what this conclusion we are going to draw from here.

(Refer Slide Time: 08:52)

Let us see, from here we would come to this one, representation of a function, as Fourier integral, that is still now rather than having a sum, that is Fourier series, the series we would be, changing to the integral. How we are going to do it, we will take the help of the, just now whatever we had learnt from the graphs, so let us see is, that is mathematically how we are going to do it.

(Refer Slide Time: 09:25)

$$f_L(x) = a_0 + \sum_{n=1}^{\infty} (a_n \cos \omega_n x + b_n \sin \omega_n x), \quad \omega_n = \frac{n\pi}{L}$$

$$L \rightarrow \infty \quad f_L(x) \rightarrow f(x)$$

$$f_L(x) = \frac{1}{2L} \int_{-L}^L f_L(t) dt + \frac{1}{L} \sum_{n=1}^{\infty} \left[ \cos \omega_n x \int_{-L}^L f_L(t) \cos \omega_n t dt + \sin \omega_n x \int_{-L}^L f_L(t) \sin \omega_n t dt \right]$$

Now, set

$$\Delta \omega = \omega_{n+1} - \omega_n = \frac{n+1}{L} \pi - \frac{n}{L} \pi = \frac{\pi}{L} \Rightarrow \frac{1}{L} = \frac{\Delta \omega}{\pi}$$

Fourier series for, function  $f_L(x)$  would be, a naught summation  $n$  is running from 1 to infinity,  $a_n \cos \omega_n x$  plus  $b_n \sin \omega_n x$ , where  $\omega_n$  of course, I am writing  $n\pi$  by  $L$ , that is rather than writhing here, as  $\cos n\pi$  by  $Lx$  like that, we are writing here. Now, substitute this  $a_n$  and  $b_n$  by the Euler's formula, for that, one more thing, we would be assuming over here, that as  $L$  is approaching to infinity,  $f_L(x)$  is approaching to  $f(x)$ ,  $f(x)$  if you do remember, we had find out the function is, 1 in the interval minus 1 to plus 1 and 0 elsewhere, that was the limit.

Moreover we would be assuming is that, wherever is required, all the integrals, and this series convergence, is existing, that is the sum of the series and the integrals are existing. Moreover we would be assuming, certain places, that is they can be interchanged, that is the summation in integration signs can be interchanged, for that, if you do remembers, you have done, uniform convergence and that kind of results. So, those results we would be assuming here, as they are happening, so let us see.

Now, a naught is  $\frac{1}{2L} \int_{-L}^L f_L(t) dt$ , I am changing this function  $x$  to  $t$  in the integral, because I am saying is that is  $f_L(x)$  is being represented at  $x$ , so all the integrals and integrant, we would be changing it to the  $t$ . So, that there is no confusion between the integral and the value at the, or thus point at, which the function we are evaluating, plus  $\frac{1}{L} \sum_{n=1}^{\infty} \left[ \cos \omega_n x, a_n \right]$  upon  $L$ , that we have taken outside, integral minus  $L$  to plus  $L$   $f_L(t) \cos \omega_n t dt$  and

plus sine omega n x integral minus L to plus L f L t sine omega n t d t, that is all these coefficients a naught a n and b n.

We had replaced it them by, Euler's formulae a naught this one for a n 1 upon L this one and for b n 1 upon L times this one. Let us see, some delta omega, this we are saying is omega n plus 1 minus omega n, omega n is n pi over L, that says is it would be, pi by L, now if L is approaching to infinity pi by L, would be approaching to 0, that is delta omega would be approaching to 0, more over 1 upon L, we could write as, delta omega upon pi.

(Refer Slide Time: 12:15)

Hence

$$f_L(x) = \frac{1}{2L} \int_{-L}^L f_L(t) dt + \frac{\Delta\omega}{\pi} \sum_{n=1}^{\infty} \left[ \cos\omega_n x \int_{-L}^L f_L(t) \cos\omega_n t dt + \sin\omega_n x \int_{-L}^L f_L(t) \sin\omega_n t dt \right]$$

$L \rightarrow \infty \quad f_L(x) \rightarrow f(x) \quad \text{And}$

$$\lim_{L \rightarrow \infty} \frac{1}{2L} \int_{-L}^L f(x) dx = 0$$

$$f(x) = \frac{\Delta\omega}{\pi} \sum_{n=1}^{\infty} \left[ \cos\omega_n x \int_{-\infty}^{\infty} f(t) \cos\omega_n t dt + \sin\omega_n x \int_{-\infty}^{\infty} f(t) \sin\omega_n t dt \right]$$

So, f L X I can write as, 1 upon 2 L minus L to plus L f L t d t plus delta omega upon pi 1 upon L, we are changing it to delta omega upon pi, summation n is running from 1 to infinity cos omega n x, integral minus L to plus L f L t cos omega n t d t, plus sine omega n x integral minus 1 to plus 1 f L t sine omega n t d t. Now, take the limit on both the sides, so as L approaches to infinity, we do know that f L X approaches to f X, and as L approaches to infinity, integral 1 upon 2 L minus L to plus L actually, f X d x minus infinity to plus infinity f X d x, this is 0.

Then f X, so now, I am taking the limit on both the sides, so f L X is approaching to f X this, where it would be, this integral would be 0. I would be getting is, delta omega upon pi, summation n is running from 1 to infinity, cos omega n x integral minus infinity to plus infinity f t cos omega n t d t plus sine omega n x integral minus infinity to plus

infinity  $\int_{-\infty}^{\infty} f(t) \sin \omega_n t dt$ . Now, what assumptions, we have taken over here, we see here, we have taken  $f \in L^1$  is approaching to  $f \in X$ .

So, wherever we were having is  $f \in L^1$ , that is approaching to  $f \in X$ , we had assumed, that all the limits integrals, and the summations they had existing, moreover the interchange is possible, what it says is, that if I take the limit over here, then I can interchange this limits with the summation sign. So, the limit am taking inside, limit with respect to  $L$ , am changing it, that is the integral minus infinity to plus infinity, moreover the limit  $f \in L^1$  is being also changed with  $f \in X$ .

So, all those assumptions on the limit, integrals on summations, we had assumed over here. So, finally, we have got,  $f \in X$  we can approximate as,  $\Delta \omega$  upon  $\pi$ , summation  $n$  is running from 1 to infinity  $\cos \omega_n x$ , integral minus infinity to plus infinity  $\int_{-\infty}^{\infty} f(t) \cos \omega_n t dt$  plus sine  $\omega_n x$ , integral minus infinity to plus infinity  $\int_{-\infty}^{\infty} f(t) \sin \omega_n t dt$ .

(Refer Slide Time: 14:40)

So

$$f(x) \equiv \frac{1}{\pi} \left[ \sum_{n=1}^{\infty} \Delta \omega \cos \omega_n x \int_{-\infty}^{\infty} f(t) \cos \omega_n t dt + \sum_{n=1}^{\infty} \Delta \omega \sin \omega_n x \int_{-\infty}^{\infty} f(t) \sin \omega_n t dt \right]$$

$\because L \rightarrow \infty \Rightarrow \Delta \omega = \frac{\pi}{L} \rightarrow 0 \quad \omega_n \rightarrow \omega$

Hence by definition of integral

$$f(x) \equiv \frac{1}{\pi} \left[ \int_0^{\infty} \left( \cos \omega x \int_{-\infty}^{\infty} f(t) \cos \omega t dt \right) d\omega + \int_0^{\infty} \left( \sin \omega x \int_{-\infty}^{\infty} f(t) \sin \omega t dt \right) d\omega \right]$$

So,  $f \in X$  now,  $\Delta \omega$  I am taking inside, the summation sign is also inside,  $1$  upon  $\pi$ . Now, rewriting the same term, summation  $n$  is running from 1 to infinity,  $\Delta \omega$  times  $\cos \omega_n x$  and then, this integral minus infinity to plus infinity  $\int_{-\infty}^{\infty} f(t) \cos \omega_n t dt$ , and again this breaking this one. So, summation  $n$  is running from 1 to infinity,  $\Delta \omega$  sine  $\omega_n x$  and then the integral minus infinity to plus infinity  $\int_{-\infty}^{\infty} f(t) \sin \omega_n t dt$ .

Now, we will use the definition of, integral you do remember, that the definition of integral, this we are changing it to, that is Since L is approaching to infinity, delta omega would be approaching to 0, omega n, now we will take is approaching to omega. Hence, by definition of the integral, we would get, f X as 1 upon pi, this summation is changing to the integral 0 to infinity cos omega x, this is the multiple of this thing. So, what we are saying is now total function, this function is fixed with respect to now our limit.

But, one thing we are taking is, omega n is approaching to omega, so we are including, it here that, this function is changing to integral f t cosine omega t d t this integral. So, now we are getting, finally 0 to infinity cos omega x into integral minus infinity to plus infinity f t cos omega t d t, whole integral with respect to omega. Similarly, the second one, integral 0 to infinity, sine omega x multiplied with integral minus infinity to plus infinity f t sine omega t d t d omega.

(Refer Slide Time: 16:32)

**Now, let**

$$A(\omega) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(t) \cos \omega t dt, \quad B(\omega) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(t) \sin \omega t dt$$

$$f(x) = \frac{1}{\pi} \left[ \int_0^{\infty} \left( \cos \omega x \int_{-\infty}^{\infty} f(t) \cos \omega t dt \right) d\omega + \int_0^{\infty} \left( \sin \omega x \int_{-\infty}^{\infty} f(t) \sin \omega t dt \right) d\omega \right]$$

$$= \frac{1}{\pi} \int_0^{\infty} [A(\omega) \cos \omega x + B(\omega) \sin \omega x] d\omega$$

**This is called representation of f(x) as Fourier Integral**

Now, rewrite it I get, assume A omega as, 1 upon pi integral minus infinity to plus infinity f t cos omega t d t, this thing we are assuming as, A omega and because this would be a function of omega, t would be integrate it out. Similarly, the other one we can assume as B omega, that 1 upon pi integral f t sine omega t d t on the whole real line minus infinity to plus infinity, then rewrite the function, then f x we could write, 1 upon pi integral, this integral again am this rewriting.

So, now this inside integral, this we are changing, this is the function of omega, so A omega and this inside integral, is B omega. So, what we would get it rewrite, 1 upon pi 0 to infinity, a omega cos omega x plus B omega sine omega x integrate it with respect to omega, this is called the representation of this function f X, as Fourier integral. Why, we are using the term Fourier, if you do remember Fourier series, we said is series of sine and cosine.

Here what I am having is, I am having an integral, which has cosine term and sine term, and it has certain coefficients, which we call A omega and B omega. In the series, we if you do remember we were having is, a n and b n and then this summation, here we are having integral, and this A omega, B omega, d omega, so we are calling it Fourier integral, what it helps.

(Refer Slide Time: 18:10)

**Theorem**

If  $f(x)$  is a piecewise continuous function in every finite interval and has a right hand derivative and a left hand derivative at every point and if the integral

$$\lim_{a \rightarrow -\infty} \int_a^0 |f(x)| dx + \lim_{b \rightarrow \infty} \int_0^b |f(x)| dx \text{ exists. } \left( \int_{-\infty}^{\infty} |f(x)| dx < \infty \right)$$

Then  $f(x)$  can be represented by Fourier Integral

$$f(x) = \int_0^{\infty} [A(\omega) \cos \omega x + B(\omega) \sin \omega x] d\omega$$

$$A(\omega) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(x) \cos \omega x dx, B(\omega) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(x) \sin \omega x dx$$

Let us see, this result, which we have find it out, theoretically what it says, if f X is a piecewise continuous function, in every finite interval and has a right hand derivative and left derivative, at every point. So, now we are not assuming, that the function is differentiable, actually we say is, that is only if the left hand derivative and right hand derivative are existing, and the function is piecewise continuous, moreover if the integral as a approaches to minus infinity of a to 0 f X d x, and b approaches to plus infinity 0, to I am sorry, it should be 0 to b, 0 to b modulus f X d x.

This must exist, this we can rewrite as, integral minus infinity to plus infinity modulus f X d x does exist, have remember it, this is call the existence of, integral of the function f X or this is simple terms we say is that the, function is integrable. Then f X can be represented by, the Fourier integral as A omega cos omega x plus B omega sine omega x integrate it, with respect omega in the interval 0 to infinity.

So, what we have got the function is, now we are not requiring the function to be, your periodic we are saying is, function is piecewise continuous, has left hand and right hand derivative at every point and the function is integrable, and the whole real line. Then, it can be represented as a Fourier integral, the form of the Fourier integral is, that integral from 0 to infinity, A omega cos omega x plus B omega sine omega x d omega, where this A omega is nothing but 1 upon pi integral minus infinity to plus infinity f X cos omega x d x, and B omega is the integral 1 upon pi, integral minus infinity to plus infinity f X sine omega x d x.

(Refer Slide Time: 20:27)

**Theorem (contd.)**

and at every point of discontinuity the  
value of Fourier integral equals to

$$\frac{1}{2}(f(x-0)+f(x+0))$$

Moreover, at every point of discontinuity, the value of the Fourier integral, equals to the, average of the left hand limit and the right hand limit, this should be x plus 0 rather than f. f of x minus 0 that means, the left hand limit at x, and f of x plus 0 that is the, right hand limit at x. So, at the point of continuity, we are having is at the can be represented, the value of the function would be equal to that Fourier integral, and at the point of

discontinuity, the value of the Fourier integral would be equal to the average of the right hand and left hand limit.

(Refer Slide Time: 21:12)

**Example**

Find the Fourier integral representation of

$$f(x) = \begin{cases} 1 & |x| < 1 \\ 0 & |x| \geq 1 \end{cases}$$

**Solution**

$$f(x) \equiv \int_{-\infty}^{\infty} [A(\omega)\cos\omega x + B(\omega)\sin\omega x] d\omega$$

$$A(\omega) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(x)\cos\omega x dx = \frac{1}{\pi} \int_{-1}^1 \cos\omega x dx$$

$$= \frac{\sin\omega x}{\pi\omega} \Big|_{-1}^1 = \frac{2\sin\omega}{\pi\omega}$$

Let us see, one example find the Fourier Integral representation of the function 1, which is 1 in the interval minus 1 to plus 1 and 0 outside, that is, this we are just having the same function. That says, we want, this kind of representation, we want an integral, which has the terms, A omega cos omega x + B omega sine omega x, so we have to find out, what is this A omega and B omega, we can find out for this function f X, we could ((Refer Time: 21:43)) write it as a function.

So, let us see, A omega what it should be, just now we had find out the formula, that 1 upon pi minus infinity to plus infinity f X cosine omega x d x, now for this function f X let us evaluate it. So, it should be, 1 upon pi minus 1 to plus 1 cos omega x d x, this is an even function, sine omega x upon pi omega, so we get 2 sine omega upon pi omega, this is what is my A omega.

(Refer Slide Time: 22:14)

$$B(\omega) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(x) \sin \omega x dx = \frac{1}{\pi} \int_{-1}^1 \sin \omega x dx = \frac{\cos \omega x}{\pi \omega} \Big|_{-1}^1 = 0$$

$$\therefore f(x) = \frac{2}{\pi} \int_0^{\infty} \frac{\sin \omega}{\omega} \cos \omega x d\omega$$

at  $x = 1$   $\frac{f(1-0) + f(1+0)}{2} = \frac{1}{2}$

And RHS

$$\frac{2}{\pi} \int_0^{\infty} \frac{\sin \omega \cos \omega x}{\omega} d\omega = \frac{1}{2} \Rightarrow \int_0^{\infty} \frac{\sin \omega \cos \omega}{\omega} d\omega = \frac{\pi}{4}$$

at  $x = 0$ ,  $f(0) = 1$  hence

$$\frac{2}{\pi} \int_0^{\infty} \frac{\sin \omega}{\omega} d\omega = 1 \Rightarrow \int_0^{\infty} \frac{\sin \omega}{\omega} d\omega = \frac{\pi}{2}$$

Now,  $B(\omega)$  would be  $\frac{1}{\pi}$  upon  $\pi$ , integral minus infinity to plus infinity  $f(x)$ , sine  $\omega x$   $dx$  evaluate it, minus 1 to plus 1 sine  $\omega x$   $dx$ , the integral is  $\cos \omega x$   $x$  upon  $\pi \omega$ , minus 1 to plus 1 this is 0, we need not to evaluate, we could have seen it, that is an odd function in the interval minus 1 to plus 1, so it should be 0. So, what we are getting is  $f(x)$  as  $\frac{2}{\pi}$  upon  $\pi$ , 0 to infinity, this is what a,  $A(\omega)$  we have got  $\frac{2}{\pi}$  sine  $\omega$  upon  $\pi \omega$ , sine  $\omega$  upon  $\omega$ ,  $\cos \omega x$   $d\omega$ , this is the Fourier representation of the function  $f(x)$ .

The theorem says, that all the point of continuities, the value of the function, at that point would be same as the value of this integral, and at the point of discontinuity, it would be the left hand and average of left hand and right hand limit. The function, if you remember we were having is, 1 in the interval minus 1 to plus 1 and 0 otherwise, so at both the points minus 1 and plus 1, the function is discontinuous.

Let us see, at point  $x$  is equal to 1, the function is discontinuous, so the left hand limit and the right hand limit  $1 - 0$  means, we are reaching towards, from the left to the 1, that is the function is 1. So, that would be 1, and from the right if I reach, it would be 0, so it would be simply  $\frac{1}{2}$  and the, what is this integral value, that is the right hand side, this integral we are saying is that, this function we are representing by this, Fourier integral.

What it would be, it would be nothing but  $\frac{2}{\pi}$  upon  $\pi$  sine  $\omega$   $\cos \omega x$ , over  $\omega$   $d\omega$ , so now I want  $x$  is equal to 1. So, what it would be, it should be equal to

half now let us write it out, it says is integral 0 to infinity, sine omega cos omega, because at x is equal to 1, it should be equal to half, this is what the theorem is saying, so integral 0 to infinity sine omega cos omega upon omega d omega, this we could write as, you see, pi by 4, because this 2 would come over here.

So, what we have done is, we have actually use the theorem, which says is that, if the function is piece wise continuous, we can represent the function by Fourier integral, and from there, actually this function, this integral of this function, we had find it out, this was the point of discontinuity. Let us take, the 0.0, at the 0.0, at the 0.0 the function is continuous, and f at 0 is 1, so by the theorem, we say is that this integral, should be equal to the value of the function.

So, what is this integral at x is equal to 0, if x is equal to 0, this cos omega x I would have as 1, so this integral would be 2 upon pi sine omega, upon omega d omega, and by the result of theorem, it should be same as the value of the function, value of the function at 0 is 1, so it should be equal to 1. Or we can say, that the integral 0 to infinity sine omega upon omega d omega is, pi by 2, so we had, you would have used, these integrals actually at many places in practical problems.

So, we are finding out these, integrals with the help of that theorem, which we are calling the Fourier representation of, any representation of any function as a Fourier integral. Let us see, cosine and sine integral, because just now in the example, we had seen that we had got, only the cosine term not the sine term, so when it will happen. As in the case of Fourier series, we had find out there if the function is, even we were getting, only cosine series, if the function was odd, we were getting only, sine series similarly, here the things will happen.

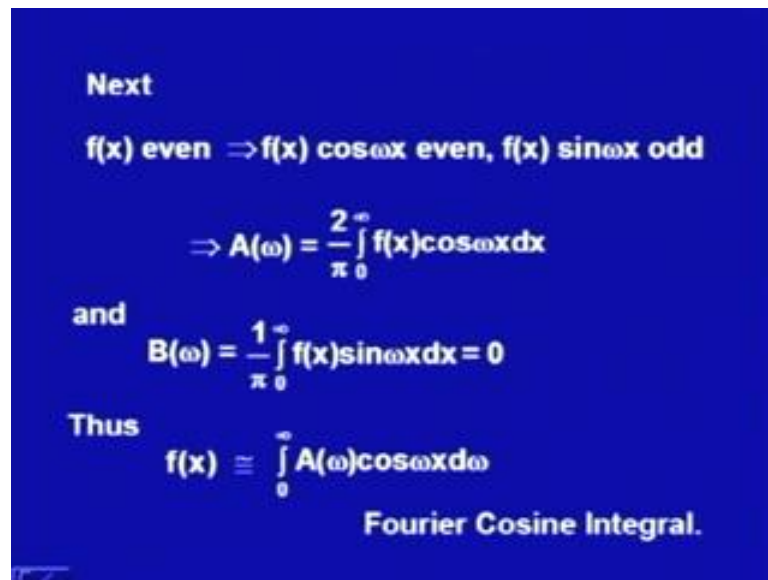

(Refer Slide Time: 26:27)

**FOURIER COSINE AND SINE INTEGRALS**  
if function  $f(x)$  is even or odd  
 $f(x)$  odd  $\Rightarrow f(x) \cos \omega x$  odd &  $f(x) \sin \omega x$  even  
 $\Rightarrow A(\omega) = \frac{1}{\pi} \int_{-\infty}^{\infty} f(x) \cos \omega x dx = 0$   
and  $B(\omega) = \frac{2}{\pi} \int_0^{\infty} f(x) \sin \omega x dx$   
Thus  $f(x) = \int_0^{\infty} B(\omega) \sin \omega x d\omega$   
**Fourier Sine Integral**

So, we say if the function is even or odd, if function is odd, then  $f(x) \cos \omega x$  is also odd, because the product of odd and even function is odd, and  $f(x) \sin \omega x$ , odd multiplied with an odd function, so product of an odd and odd function is even. So,  $f(x) \sin \omega x$  would be even, what it says is, if the function is odd, and the  $A(\omega)$  is  $\frac{1}{\pi} \int_{-\infty}^{\infty} f(x) \cos \omega x dx$ . This will always be 0, because ((Refer Time: 27:05)) integral is, from minus infinity to plus infinity.

Remember that, in the definite integral property, we were having is actually minus a to plus a here, we are taking it minus infinity to plus infinity. So, we are taking it is a limit point, and we are assuming that, all those integrals, are existed that is, why we are taking it to be 0. And  $B(\omega)$  is,  $\frac{2}{\pi} \int_0^{\infty} f(x) \sin \omega x dx$ , because  $f(x) \sin \omega x$  is even, so we can write it as, 2 times that integral, so  $\frac{1}{\pi} \int_{-\infty}^{\infty} f(x) \sin \omega x dx$  would be nothing but 2 times  $\frac{1}{\pi} \int_0^{\infty} f(x) \sin \omega x dx$ , so this is  $B(\omega)$ . And what we will get, we will get, only sine integral, so  $f(x)$  would be only,  $\int_0^{\infty} B(\omega) \sin \omega x d\omega$ , where  $B(\omega)$  is, this one, this is Fourier sine integral.

(Refer Slide Time: 28:01)

Next

$f(x)$  even  $\Rightarrow f(x) \cos \omega x$  even,  $f(x) \sin \omega x$  odd

$$\Rightarrow A(\omega) = \frac{2}{\pi} \int_0^{\infty} f(x) \cos \omega x dx$$

and

$$B(\omega) = \frac{1}{\pi} \int_0^{\infty} f(x) \sin \omega x dx = 0$$

Thus

$$f(x) \equiv \int_0^{\infty} A(\omega) \cos \omega x d\omega$$

Fourier Cosine Integral.

Now, if the function is, even what it says is,  $f(x) \cos \omega x$  would be even, because the product of, even function with an, even function will give me, even function and product of, even function with odd function,  $f(x) \sin \omega x$  is an odd function. So,  $f(x) \sin \omega x$ , this would be odd, that says is, when we calculate this  $A(\omega)$  and  $B(\omega)$ ,  $A(\omega)$  the function is even. So, it would be  $2 \int_0^{\infty} f(x) \cos \omega x dx$ , when it is odd, then  $B(\omega)$  would be, simply 0, it should be  $\int_{-\infty}^{\infty} f(x) \sin \omega x dx$  plus infinity.

Thus, I can represent  $f(x)$  as  $\int_0^{\infty} A(\omega) \cos \omega x d\omega$ , only cosine integral, so as in the case of Fourier sine series and cosine series we have sine, here also we are finding out, if the function is even, we get Fourier only Fourier cosine integral, and if the function is odd we get, only Fourier sine integral. Now, where we are using, so use of this Fourier integrals, in evaluation of, integrals we had seen one example, where we had integrated certain functions, which we were not able to integrate as such let us see one example.

(Refer Slide Time: 29:31)

**Use Of Fourier Integral In Evaluation  
of Integrals**

**Example**  
Find the Fourier cosine and sine integrals for  
 $f(x) = e^{-kx}, x > 0, k > 0$

**Solution**

$$A(\omega) = \frac{2}{\pi} \int_0^{\infty} e^{-kx} \cos \omega x \, dx$$

$$A(\omega) = \frac{2}{\pi} \left[ -\frac{1}{k} e^{-kx} \cos \omega x \right]_0^{\infty} - \frac{\omega}{k} \int_0^{\infty} e^{-kx} \sin \omega x \, dx$$

$$= \frac{2}{\pi} \left[ \frac{1}{k} - \frac{\omega^2}{k^2} \int_0^{\infty} e^{-kx} \cos \omega x \, dx \right]$$

Find the Fourier cos and sine integral, for the function, e to the power minus k x for x positive and k positive, let us try it. A omega, the function e to the power minus k x for, x positive and k positive. So, we are, having this minus infinity to plus infinity, so we should start this, 0 to infinity, because the function from minus infinity to 0 is 0. So, it is 2 upon pi 0, we want cosine integral, so 2 upon pi 0 to infinity, e to the power minus k x, cos omega x d x, integrate this one.

We get, 2 upon pi, minus 1 upon k e to the power minus k x, this is integration by part this function we are taking as integrating function this as the differentiation function, cos omega x, 0 to infinity, minus omega by k integral 0 to infinity, e to the power minus k x sine omega x d x. Which is 2 upon pi, simplification 1 upon k minus omega square upon k square, integral 0 to infinity, e to the power minus k x, cos omega x d x.

Now you see this is what a omega, omega was, if I just remove this constant over here, just see the what is the integrant, e to the power minus k x, sine cosine omega x, here also we are getting is e to the power minus k x cosine omega x. The coefficient 2 upon pi, that is also here, what it says is, I have again came to the same kind of integral, what it says now, I take this integral, 2 upon pi, that is it is omega square upon k square times A omega

(Refer Slide Time: 31:14)

$$\Rightarrow \left(1 + \frac{\omega^2}{k^2}\right) A(\omega) = \frac{2}{\pi} \cdot \frac{1}{k} \quad \Rightarrow A(\omega) = \frac{2}{\pi} \frac{k}{k^2 + \omega^2}$$

Hence Fourier Cosine Integral:

$$e^{-kx} = f(x) = \frac{2k}{\pi} \int_0^{\infty} \frac{\cos \omega x}{k^2 + \omega^2} d\omega \quad x > 0, k > 0$$

$$\Rightarrow \int_0^{\infty} \frac{\cos \omega x}{k^2 + \omega^2} = \frac{\pi}{2k} e^{-kx} \quad x > 0, k > 0$$

Now,

$$B(\omega) = \frac{2}{\pi} \int_0^{\infty} f(x) \sin \omega x dx = \frac{2}{\pi} \int_0^{\infty} e^{-kx} \sin \omega x dx$$

So, what we are getting is, 1 plus omega square upon k square times a omega is equal to, 2 upon pi into 1 upon k, what it says a omega is 2 upon pi, k upon k square upon omega square. Now, you see, we were not able to calculate, that integral e to the power minus k x sine omega x d x, directly we had calculated it, using this recurrence relation you could say, similarly, so Fourier cosine integral of this function, e to the power minus k x, we could write, 2 k upon pi, integral 0 to infinity, cos omega x, upon k square omega square d omega.

Why, A omega cos omega x d omegas, so A omega is 2 k upon pi times k square plus omega square. So, pi is here, k square plus omega square inside, because the integral is with respect to omega, e to the power minus k x f X is 2 k upon pi integral 0 to infinity cos omega x upon k square plus omega square d omega, for x positive and k positive, from here, what we are getting, we are getting that, integral 1 to infinity cos omega x upon k square omega square d omega, is equal to pi upon 2 k times e to the power minus k x, so we are evaluating, this integral with the help of this Fourier cosine integral.

So, now let us move to the Fourier sine integral, so for this, we require B omega, what is the formula for B omega, 2 upon pi integral 0 to infinity f x sine omega x d x, now my f X is, e to the power minus k x. So, we are having is 2 upon pi integral 0 to infinity, e to the power minus k x sine omega x d x, let us evaluate this integral by parts.

(Refer Slide Time: 33:11)

Integration by parts gives,

$$\begin{aligned}
 B(\omega) &= \frac{2}{\pi} \int_0^{\infty} e^{-kx} \sin \omega x \, dx \\
 &= \frac{2}{\pi} \left[ -\frac{1}{k} e^{-kx} \sin \omega x \Big|_0^{\infty} - \left\{ \frac{\omega}{k} \int_0^{\infty} e^{-kx} \cos \omega x \, dx \right\} \right] \\
 &= \frac{2}{\pi} \left[ \frac{\omega}{k} \left\{ -\frac{1}{k} e^{-kx} \cos \omega x \Big|_0^{\infty} + \frac{\omega}{k} \int_0^{\infty} e^{-kx} \sin \omega x \, dx \right\} \right] \\
 &= \frac{2}{\pi} \left[ \frac{\omega}{k^2} - \frac{\omega^2}{k^2} \int_0^{\infty} e^{-kx} \sin \omega x \, dx \right]
 \end{aligned}$$

So,  $B(\omega)$  is this integral, we are going to evaluate it by parts, we will take,  $e^{-kx}$  as the integrating function and  $\sin \omega x$  as the differentiating function. So, first integral,  $\frac{1}{k} e^{-kx} \sin \omega x$  evaluated from 0 to infinity, minus  $\frac{\omega}{k}$  integral 0 to infinity,  $e^{-kx} \cos \omega x \, dx$ . Now, when we are evaluating it, as  $x$  approaches to infinity,  $e^{-kx}$  would have pushed to 0.

So, this value would be 0, at 0  $\sin \omega x$ , that is  $\sin 0$  would be 0, so, this would give us 0, and what is being left is,  $\frac{2}{\pi} \frac{\omega}{k}$ , minus  $\frac{\omega}{k}$  integral this again evaluating by the parts,  $e^{-kx} \cos \omega x$ , evaluated from 0 to infinity, plus  $\frac{\omega}{k}$  integral 0 to infinity,  $e^{-kx} \sin \omega x$ . Now, you see, we had again come to the, same integrands, which was in the  $B(\omega)$ , the coefficient is 2 ((Refer Time: 34:24))  $\frac{2}{\pi}$  is outside, so we can again, take this as  $B(\omega)$ .

Let us evaluate, this function, as  $x$  approaches to plus infinity,  $e^{-kx}$  will approach to 0, and as  $x$  approaches  $x=0$ ,  $\cos 0$  is 1,  $e^{-k \cdot 0}$ , that is this is also 1. So, what we are getting is,  $\frac{2}{\pi} \frac{\omega}{k^2}$ , minus  $\frac{\omega}{k^2}$  integral 0 to infinity  $e^{-kx} \sin \omega x \, dx$ , this integral with  $\frac{2}{\pi}$  is  $B(\omega)$ .

(Refer Slide Time: 35:02)

$$\Rightarrow \left(1 + \frac{\omega^2}{k^2}\right) B(\omega) = \frac{2\omega}{\pi k^2} \Rightarrow B(\omega) = \frac{2\omega}{\pi(k^2 + \omega^2)}$$

$$\therefore f(x) = e^{-kx} = \int_0^{\infty} \frac{2\omega}{\pi(k^2 + \omega^2)} \sin \omega x d\omega = \frac{2}{\pi} \int_0^{\infty} \frac{\omega \sin \omega x}{k^2 + \omega^2} d\omega$$

$$\Rightarrow \int_0^{\infty} \frac{\omega \sin \omega x}{k^2 + \omega^2} d\omega = \frac{\pi}{2} e^{-kx} \quad x > 0, k > 0$$

'Laplace integrals'

$$\int_0^{\infty} \frac{\cos \omega x}{k^2 + \omega^2} d\omega = \frac{\pi}{2k} e^{-kx}$$

$$\int_0^{\infty} \frac{\omega \sin \omega x}{k^2 + \omega^2} d\omega = \frac{\pi}{2} e^{-kx} \quad x > 0, k > 0$$

So, we can get it as,  $1 + \omega^2$  upon  $k^2$  times  $B(\omega)$  is equal to  $2\omega$  upon  $\pi k^2$ , this says  $B(\omega)$  is,  $2\omega$  upon  $\pi(k^2 + \omega^2)$ , thus, what we are getting  $f(x)$ , which is same as,  $e^{-kx}$  that can be represented as a Fourier sine integral  $\int_0^{\infty} \frac{2\omega}{\pi(k^2 + \omega^2)} \sin \omega x d\omega$ . And, from here, what we are getting is,  $\frac{2}{\pi} \int_0^{\infty} \frac{\omega \sin \omega x}{k^2 + \omega^2} d\omega$ , so this integral is equal to,  $\frac{\pi}{2} e^{-kx}$ , again for  $x$  positive and  $k$  positive.

So, we had evaluated, this integral with the help of, Fourier sine integral, these two integrals, just now, which we had evaluated, they are called actually, Laplace integrals. So, what we are calling Laplace integrals, the integral  $\int_0^{\infty} \frac{\cos \omega x}{k^2 + \omega^2} d\omega = \frac{\pi}{2k} e^{-kx}$ , and integral  $\int_0^{\infty} \frac{\omega \sin \omega x}{k^2 + \omega^2} d\omega = \frac{\pi}{2} e^{-kx}$ , both these integrals are valid for,  $x$  positive and  $k$  positive, these are known as Laplace integrals.

So, we had seen that Fourier integral, Fourier sine and cosine integrals and we had used them for evaluation of, certain integrals. Now let us, move to the today's topic, that is the transform, Fourier transform, we are saying, now before moving to the Fourier transform, let us first move to the, Fourier cosine and sine transforms.

(Refer Slide Time: 37:02)

**FOURIER COSINE AND SINE TRANSFORMS**

An integral transform is a transformation that produces a new function, from a given function, and new function depends on different variable and appear in the form of integral.

what is the transform, and integral transform is a transform, that produces a new function, from a given function, and new function, depends on the different variable and appear in the form of, integral. You had already done, one transform called the Laplace transform, here we are moving to this, Fourier cosine and sine transform.

(Refer Slide Time: 37:24)

**Fourier Cosine Transform**

$$f(x) = \int_0^{\infty} A(\omega) \cos \omega x d\omega,$$

with

$$A(\omega) = \frac{2}{\pi} \int_0^{\infty} f(x) \cos \omega x dx = \hat{f}_c(\omega)$$

Fourier Cosine transform of  $f(x)$

and

$$f(x) = \int_0^{\infty} F_c(\omega) \cos \omega x d\omega$$

is Inverse Fourier Cosine Transform

$$\hat{f}_c(\omega) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} f(x) \cos \omega x dx$$

So, first let us see, Fourier cosine transform, we want the function should be represented as the integral, of something and that, should come out to be as another, function in another variable. So,  $f(x)$  we do know by Fourier integral, can be given as, 0 to infinity,

integral 0 to infinity,  $A \int_0^\infty \cos \omega x \, d\omega$ , when  $f(x)$  is even. Now, with  $A = \frac{2}{\pi}$ ,  $\int_0^\infty f(x) \cos \omega x \, dx$ , this  $A \int_0^\infty$ .

Now you see, we have got, for this function  $f(x)$ , we have got one integral, which is again a function, in some other variable, this we are calling, Fourier cosine transform,  $A \int_0^\infty$  and moreover, what we are getting is, if I again integrate this,  $A \int_0^\infty$  with multiplication with this function  $\cos \omega x \, d\omega$ , with respect to  $\omega$ , we would get back my function  $f(x)$ . So, this  $A \int_0^\infty$ , this is called the Fourier cosine transform of  $f(x)$ , and  $f(x) = \int_0^\infty f_c(\omega) \cos \omega x \, d\omega$ , this  $f_c$  is not this capital  $F_c$ , this is actually this  $f_c(\omega)$  is, the inverse Fourier cosine transform.

So, what we are getting is, in ((Refer Time: 39:08)) read this, you have already done this Laplace transform, in the Laplace transform you had not find out, what is the inverse Laplace transform, inverse Laplace transform, you had find out. That is, if the function, if a function is a Laplace transform, of this function, then that function you call the inverse Laplace transform, of the new function.

But here, we do have a formula that is given this function, this Fourier cosine transform, without moving that is, which from, which function we had obtained this function, we could get the, inverse Fourier cosine transform that is again a transform in the two definition of the transform. So, another variant is, here in transform I had used, that is cosine transform, I had used the coefficient,  $\frac{2}{\pi}$  this constant, and the inverse Fourier transform, I have not used any coefficient, but some variant is, that is both the places, they coefficient is being used as, square root  $\frac{2}{\pi}$ , that does not matter. In practical application, either you use this, constant at both the places that is in the cosine transform and the inverse cosine transform, or you use only  $\frac{2}{\pi}$  in the cosine transform, and do not use any coefficient in the inverse transform.

(Refer Slide Time: 40:25)

**Fourier Sine Transform**

$$f(x) = \int_0^{\infty} B(\omega) \sin \omega x d\omega$$

where  $B(\omega) = \int_0^{\infty} f(x) \sin \omega x dx$

**Fourier Sine Transform of f (x)**

Thus  $\hat{f}_s(\omega) = \frac{2}{\pi} \int_0^{\infty} f(x) \sin \omega x dx$

and  $f(x) = \int_0^{\infty} \hat{f}_s(\omega) \sin \omega x d\omega$

**Inverse Fourier Sine Transform**

Similarly, Fourier sine transform, is been obtained using the Fourier sine integral 0 to infinity B omega sine omega x d omega, where d omega is nothing but integral 0 to infinity f X sine omega x d x. This is Fourier sine transform of f X, and we would denote it by, f s hat omega, and right 2 upon pi 0 to infinity f X sine omega x d x, and f X which is, now B omega, I am writing it as f s hat omega f s hat omega sine omega x d omega, this is inverse Fourier sine transform. So, one function we have got in omega, from the function n x, then function in omega I was having, and I got the function in x. So, both are the transform sine transform and inverse Fourier sine transform.

(Refer Slide Time: 41:36)

**Sometimes the constant differs**

$$\hat{f}_c(\omega) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} f(x) \cos \omega x dx$$

$$f(x) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} \hat{f}_c(\omega) \cos \omega x d\omega$$

$$\hat{f}_s(\omega) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} f(x) \sin \omega x dx$$

$$f(x) = \sqrt{\frac{2}{\pi}} \int_0^{\infty} \hat{f}_s(\omega) \sin \omega x d\omega$$

Let us see, some examples of these kinds as, I said is sometimes this constant differ, so let me just write, it out these constants, in nice definitions I had used,  $2$  upon  $\pi$  in the transforms, and I have not used, any coefficient in the inverse transform. Sometimes both the places this, coefficient is square root  $2$  upon  $\pi$  is being used, so that, similarity can be maintained.

So, we do get,  $f_c \hat{\omega}$ , that is the Fourier cosine transform as, square root  $2$  upon  $\pi$ , integral  $0$  to infinity  $f(x) \cos \omega x dx$  and inverse Fourier cosine transform as,  $f(x)$  as square root  $2$  upon  $\pi$   $0$  to infinity  $f_c \hat{\omega} \cos \omega x d\omega$ . Similarly, for sine transform, square root  $2$  upon  $\pi$   $0$  to infinity  $f(x) \sin \omega x dx$  and inverse Fourier transform, again the coefficient, square root  $2$  upon  $\pi$  integral  $0$  to infinity  $f_s \hat{\omega} \sin \omega x d\omega$ .

(Refer Slide Time: 42:35)

**Example**

Find the Fourier sine transform and Fourier cosine transform for the functions

$$f(x) = \begin{cases} 1 & 0 < x < 1 \\ -1 & 1 < x < 2 \\ 0 & x \geq 2 \end{cases}$$

**Solution**

The Fourier cosine Transform

$$\hat{f}_c(\omega) = \frac{2}{\pi} \int_0^{\infty} f(x) \cos \omega x dx$$

$$\Rightarrow \hat{f}_c(\omega) = \frac{2}{\pi} \left[ \int_0^1 \cos \omega x dx - \int_1^2 \cos \omega x dx \right]$$

Come to the example; find the Fourier sine transform and Fourier cosine transform, for the function, which is  $1$  in the interval  $0$  to  $1$  minus  $1$  in the interval  $1$  to  $2$  and  $0$  for  $x$  greater than  $2$ . So, now find out the transform, first Fourier cosine transform, I am using the formula, where the coefficient I am using as,  $2$  upon  $\pi$ , so  $f_c \hat{\omega}$  would be,  $2$  upon  $\pi$  integral  $0$  to infinity  $f(x) \cos \omega x dx$ .

Now,  $f(x)$  is this function, which is for, which we have to calculate, this says is,  $f_c \hat{\omega}$  would be,  $2$  upon  $\pi$  integral  $0$  to  $1$  the function is  $1$ . So one time,

that is cosine omega x d x and in the interval 1 to 2 it is minus 1, so minus sign I have taken outside, it should be 1 to 2, not 0 to 2, it should be 1 to 2, 1 to 2 cos omega x d x.

(Refer Slide Time: 43:48)

$$\begin{aligned} \Rightarrow \hat{f}_c(\omega) &= \frac{2}{\pi\omega} \left[ \sin\omega x \Big|_0^1 - \sin\omega x \Big|_1^2 \right] \\ &= \frac{2}{\pi\omega} \left[ \sin\omega - \sin 2\omega + \sin\omega \right] \\ &= \frac{2}{\pi\omega} \left[ 2\sin\omega - \sin 2\omega \right] \end{aligned}$$

**The Fourier sine Transform**

$$\hat{f}_s(\omega) = \frac{2}{\pi} \int_0^{\infty} f(x) \sin\omega x dx$$

$$\therefore \hat{f}_s(\omega) = \frac{2}{\pi} \left[ \int_0^1 \sin\omega x dx - \int_1^2 \sin\omega x dx \right]$$

Now, evaluate these integrals, 2 upon pi omega sine omega, because integral of cos omega x is, sine omega x upon omega, evaluated 0 to 1, minus sine omega x, evaluated 1 to 2, this omega, we have taken outside. We get, sine omega sine x is 0, that is 0, sine 2 omega plus sine omega, it says is 2 upon pi omega times, 2 sine omega minus sine 2 omega, this is what is my Fourier cosine transform, now find out Fourier sine transform, again I would use the coefficient 2 upon pi.

So 2 upon pi integral 0 to infinity f X sine omega x d x, so put the function is minus, function is 1, in 0 to 1 and minus 1, in 1 to 2. So, break this integral 0 to 1, sine omega x d x minus integral 1 to 2 sine omega x d x it is 0 elsewhere, so we are assuming, that the integral of 0 function is always 0.

(Refer Slide Time: 45:08)

$$\begin{aligned}\Rightarrow \hat{f}_s(\omega) &= \frac{2}{\pi\omega} \left[ -\cos\omega x \Big|_0^1 + \cos\omega x \Big|_1^2 \right] \\ &= \frac{2}{\pi\omega} [1 - \cos\omega + \cos 2\omega - \cos\omega] \\ &= \frac{2}{\pi\omega} [1 - 2\cos\omega + \cos 2\omega] \\ &= \frac{2}{\pi\omega} [1 - 2\cos\omega + 2\cos^2\omega - 1] \\ &= \frac{4\cos\omega}{\pi\omega} (\cos\omega - 1)\end{aligned}$$

Evaluate this integral, integral of sine omega x is minus cos omega x upon omega, both the places am having the integrant as sine omega x, so omega, just write it, write outside, minus cosine omega x, evaluate it 0 to 1 plus sine omega x, evaluated from 1 to 2. Now, evaluate it, 2 upon pi omega cos first it is minus sign, so first I am taking 0, cos 0 is 1, at x is equal to 1, it is minus cos omega, then cos 2 omega minus cosine omega. So, what we have got finally, 2 upon pi omega, 1 minus, 2 cos omega plus cos 2 omega, this is what is our, Fourier sine transform of the given function.

We can simplify little bit more, cos 2 omega, we can write as 2 cosine square omega minus 1, so we get 1 minus 2 cos omega plus 2, cos square omega minus 1, we could write it as, 4 cos omega upon pi omega, cosine omega minus 1, simplified it that is all. So, we are getting this as the, Fourier sine transform of the, given function, so today we had, learn how to represent, any function, which is not periodic, as Fourier integral, or we said is, that is representation of a function, as a Fourier integral, then we had learn, that is depending upon the property of the function, that is the function is odd or even.

We can find it out whether, it is or we can represent it, as a Fourier sine integral or Fourier cosine integral, and we can find out the transform, then we had came to the transform, and we had learn the, Fourier sine transform and cosine transform. What is the use of this representation of function as integral or these transforms, for integrals we had used it, for evaluation of certain integrals, which as such we were not able to evaluate.

Fourier transforms, we had started with cosine and sine transform, and next lecture we will continue with it, and we will see some properties and then we will move to the, Fourier transforms. So, that is all for today's lecture.

Thank you
