**Lecture - 23**  
**Three Dimensional Laplace Equations**

Welcome to the lecture series and differential equations for under graduating students, today's topic is Three Dimensional Laplace Equations. We are learning about some important partial differential equations, which are very important in application engineering and physics. In that series today we will learn about three dimensional Laplace equations.

(Refer Slide Time: 00:50)

**Three Dimensional Laplace Equation**

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$

**Gravitation, Electrostatics, steady-state heat flow and fluid flow, etc.**

**Potential Theory: Theory of solution of Laplace equation is called Potential Theory**

**Harmonic Function: Solutions which have continuous partial derivatives are called the Harmonic Function**

You have seen an example, that second order linear equation  $\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$ . This is three dimensional Laplace equation, it is being called in three dimensions since we are having three co ordinates x y and z and here is the function of x y and z only, we are not having it is independent of t. This left hand side of this equation is called the Laplacian, this is very important equation in physics as well as in engineering applications. It is arising mainly gravitation electrostatics steady state heat flow and steady state fluid flow all the steady state it is coming.

The solution that is how to find out the solution of this equation theory of solution of this Laplace equation is called potential theory. So, we are also calling it potential theory that is understanding the solution as three dimensional Laplace equations. The solution if it is it is partial derivatives are continuous that is solutions, which have continuous partial derivatives they are called harmonic function.

(Refer Slide Time: 02:09)

**Gravitational Potential**

Gravitational potential  $u$  at  $(x, y, z)$  resulting from a single mass located at  $(x_0, y_0, z_0)$

$$u(x,y,z) = \frac{c}{r} = \frac{c}{\sqrt{(x-x_0)^2 + (y-y_0)^2 + (z-z_0)^2}}$$

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$

Similarly, if mass is distributed in a region  $T$  in space with density  $\rho(x_0, y_0, z_0)$  its potential  $u$  at  $(x, y, z)$ , not occupied by mass

$$u(x,y,z) = k \iiint_T \frac{\rho(x_0, y_0, z_0)}{r} dx_0 dy_0 dz_0$$

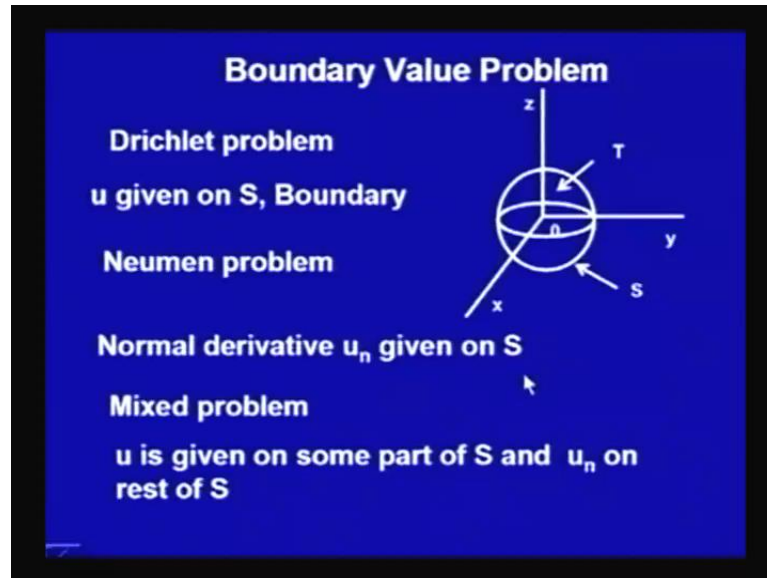

Let us, come to the one application that is gravitational potential we have learnt in physics that gravitational potential  $u$  at  $x, y, z$  resulting from a single mass located at the point  $x_0, y_0, z_0$  can be given as the function as  $u(x, y, z) = c/r$ . Where  $c$  is a constant and  $r$  is the distance between the point where this mass is located at  $x_0, y_0, z_0$  at the point at which we are calculating this potential  $x, y, z$ .

So, we do get is that we could write the distance as  $c$  upon square root of  $(x - x_0)^2 + (y - y_0)^2 + (z - z_0)^2$ . If we just apply this  $\nabla^2 u$  over  $\partial x$  and  $\nabla^2 u$  over  $\partial y$   $\nabla^2 u$  over  $\partial z$  we find it out that Laplacian of this is 0, that is it is satisfying this Laplace equation.

Now, if similarly we define, the mass is distributed in the region  $T$  in the space with density  $\rho(x_0, y_0, z_0)$ , its potential  $u$  at the point  $x, y, z$  not occupied by the mass is given as  $k$  times integral on the region  $T$ ,  $\rho$  of  $x_0, y_0, z_0$  upon  $r$   $dx_0 dy_0 dz_0$ .

Again, this will satisfy our Laplace equation, since this integral is with respect to  $x$ ,  $y$ , and  $z$  and  $\rho$  is not depending upon the point  $x$ ,  $y$ , and  $z$ . And again  $1/r$  has the Laplacian 0, so we do have that this will also satisfy this one.

(Refer Slide Time: 04:02)

So from here, let us move to the theory of solving this Laplace equation, for solving of the Laplace equation practically it is resulting in the boundary value problems. We define the boundary value problems, because we are having is that the reason is three dimensional, so it is three dimensional one. So, let us here is the example for a sphere you could any three dimensional mass in which we are interested the reason is the three dimensional solid cube, and we do have it is been covered by a surface that is we are calling  $S$ .

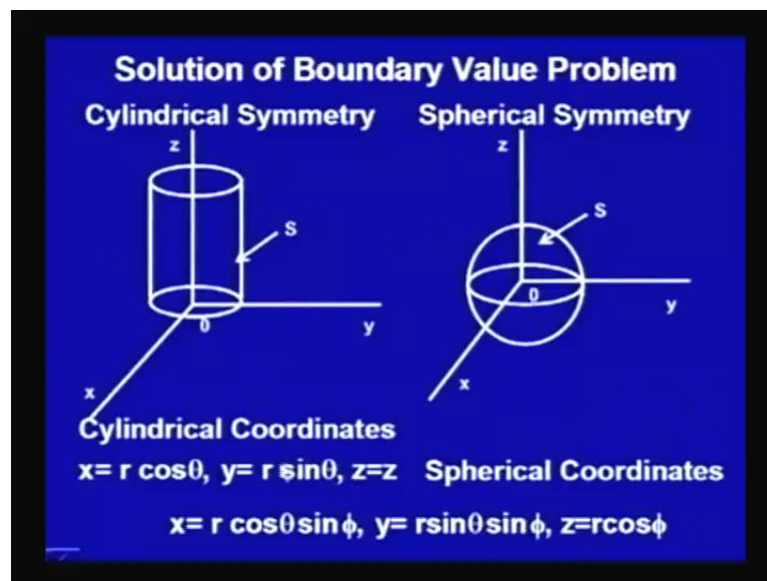

So, we define the three kind of boundary value problem, first boundary value problem or Dirichlet problem that we are calling in which the boundary condition is given on the surface that is the boundary of the region, that is  $u$  is given on  $s$  that is boundary. Second kind of boundary value problem or that we are calling Neuman problem, in which the boundary condition for the rather than for given for the  $u$ , we have been given that is normal derivative of  $u$  is been defined on the or has been prescribed on the boundary  $S$ .

And, in the third coming of boundary value problems are called the mixed problems in which any portion of boundary  $S$   $u$  is been prescribed and the rest of the portion of  $S$  the normal derivative,  $u$  is prescribed. We have seen that in two dimensional problems or

two dimensional Laplace differential equations also, we have seen that there reason was our applinary.

Here, we are having the reason is three dimensional solid, there we used to have the reason was the preliminary theorem and the boundary was the curve here boundary would be the surface. In the similar manner we have defined Drichlet problem normal derivative this Neumen problem and mixed problem. So, let us say we would start with the Drichlet problem first that is when the boundary condition is the u is defined at the boundary S surface S. So, solving it we do require is that we first actually make the change of co-ordinates or change of variables, the co-ordinates x y z they are the variables. So, we change the variables in such a manner that the region S that is the surface S becomes more simplified.

(Refer Slide Time: 06:33)

So, in that one, first we see if my surface is having cylindrical symmetry, so the solution of boundary value problem we will first see if the surface is having cylindrical symmetry that says is suppose let us say for example, my surface is that the my region is this cylinder and surface is that is for boundary condition we are defining the surface of this cylinder S.

Then, we would change my Laplace equation into the cylindrical co-ordinates, what are the cylindrical co-ordinates? They have been defined that is we are transforming x y and

z the Cartesian co-ordinates into the co-ordinates r theta and z, where the relationship between them is x is r cos theta y is r sine theta and z is equal to z.

We will learn little bit later, that is how they are been acting, similarly, suppose my problem says that the boundaries is spherical symmetry that is we are having the reason is some ball and the surface is itself sphere. So, let us say this is the reason is this the ball and in the surface is of this one, so we do have that surface is boundary is this sphere.

Then, we would like to change my Laplace equation from this Cartesian co-ordinates that is x y z to the spherical co-ordinates, what are the spherical co-ordinates? They are been given in the terms of r theta and phi and the relationship between x y z and r theta phi are been defined in this relation, that is x is r cos theta sine phi y as r sine theta sine phi and z as r cos phi. Let us see first that is what these co-ordinates and that is, what are the cylindrical co-ordinates, what are this spherical co-ordinates and how we are transforming our Laplace equation into these new variables.

(Refer Slide Time: 08:35)

**Laplace Equation in Cylindrical Coordinates**

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$

**Cylindrical Coordinates**  
 $x = r \cos \theta, y = r \sin \theta, z = z$   
 $r = \sqrt{x^2 + y^2}, \theta = \tan^{-1}(y/x), z = z$   
 $\Rightarrow r_x = \frac{x}{r}, r_y = \frac{y}{r}, \theta_x = -\frac{y}{r^2}, \theta_y = \frac{x}{r^2}$   
 $r_{xx} = \frac{1}{r} - \frac{x^2}{r^3}, r_{yy} = \frac{1}{r} - \frac{y^2}{r^3}, \theta_{xx} = \frac{2xy}{r^4}, \theta_{yy} = \frac{-2xy}{r^4}$

The slide also includes a 3D diagram of cylindrical coordinates. It shows a Cartesian coordinate system with x, y, and z axes. A point in space is defined by its cylindrical coordinates (r, θ, z). The radial distance r is shown in the xy-plane, the angle θ is measured from the positive x-axis, and the vertical height z is along the z-axis.

So, let us see 1 by 1 Laplace equation in cylindrical co-ordinates, so this is our given Laplace equation del 2 u over del x 2 plus del 2 u over del y 2 plus del 2 u over del z 2 is equal to 0, which is defined in the variables x y and z. Now, we want to define it in the terms of new variables, which we are calling cylindrical co-ordinates. Let us see, what are what we mean by cylindrical co-ordinates, as I said is that if my surface is having cylindrical symmetry. It will remember that is we are having is that cylinder is circular

and base points are you says that any cross section is circle, while you do have that height is straight line. So, that is how we are defining, that is in this three dimensional space any point as in the Cartesian co-ordinates we are defining this point as  $x y z$

Now, I would represent these point with three co-ordinates now  $r$   $\theta$  and  $z$ ,  $z$  is same thing that is if I take, what is the distance along the  $z$  axis of this point from the  $x y$  plane. So, we do have this simple Cartesian, in from the  $x y$  plane whatever the distance from this  $x y$  plane to this point  $z$  we are having that is if I drop a perpendicular from this point to the  $x y$  plane this distance this height would be called  $z$ .

So, this is what limit, but what we are having is  $x y$  plane when we talk about that is this one would be this part. So here, if you do remember in the single dimensional one, we are defining polar co-ordinates. So we define, here that is because of circle we are defining the polar co-ordinates that is the point which is coming under  $x y$  plane for that the distance from the origin  $r$  and the angle it is making with the  $x$  axis that is  $\theta$ .

So, what now this point we are defining as this point has been transported to the  $x y$  plane and in  $x y$  plane we are using the co-ordinate system  $r$  and  $\theta$  and this is  $z$ . So, this is what we are having is cylindrical co-ordinates from the polar angle we do know if I am denoting this  $r$  as the distance from origin to this point if this point in  $x y$  plane is  $x$  into  $y$ .

Then, we do know that  $x$  is nothing, but  $r \cos \theta$  and  $y$  is nothing but  $r \sin \theta$   $z$  is same as  $z$ , since we want to change my Laplace equation into these new variables  $r$   $\theta$  and  $z$  that is says is this derivatives of the function that is the function  $u x y z$ , now we would write it as  $u r \theta z$ . So, when we are changing it so this derivative with respect to  $x y$  and  $z$  that we have to change the derivative with respect to  $r y r \theta$  and  $z$ . So,  $z$  is same as  $z$  and that is the third co-ordinate itself.

So, we would first concentrate on this change of  $x$  and  $y$  into  $r$  and  $\theta$ ; that means, rather than talking about this three dimensional one we will first talk about the two dimensional one. And then we will add up the third one as such, so if that if says is now we would treat  $u$  as a function of  $x$  and  $y$  and then we want to change the variables from  $x$  and  $y$  to  $r$  and  $\theta$  using this relationship.

So, what the things you we do know that we will use the chain rule and accordingly we would find it out, so let us write this  $r$  and  $\theta$  in the terms of  $x$  and  $y$ . We do know that  $r$  would be nothing but square root of  $x^2 + y^2$   $\theta$  is nothing but  $\tan^{-1} y/x$  and  $z$  is equal to  $z$ , since we are concentrating on  $x$  and  $y$ . Then we would try to use the derivatives of  $r$  and  $\theta$  with respect to  $x$  and  $y$ , because both  $r$  and  $\theta$  are just the function of  $x$  and  $y$  only.

So, from here we do get the derivative of  $r$  with respect to  $x$ , so now, we are writing the partial derivative and we are using this notation rather than using  $\frac{\partial r}{\partial x}$  just for the space place we using this kind of notation, where  $r_x$  means it is the derivative of  $r$  partial derivative of  $r$  with respect to  $x$ . Similarly, if I do have the subscript  $y$  it says is that the partial derivative of  $r$  with respect to  $y$  and so on.

So, if I partially differentiate this one we do get is that we would get  $1/2\sqrt{x^2 + y^2}$  that is in the denominator. And the derivative of this with respect to  $x$  would be  $2x$ , so we would be getting is  $x/r$ , similarly the partial derivative of  $r$  with respect to  $y$  we would get  $y/r$  partial derivative of  $\theta$  with respect to  $x$ .

The derivative of  $\tan^{-1} x$  we do know  $1/(1+x^2)$ , so using that  $1$ , we do get it as  $1/(1+y^2/x^2)$  then the derivative of  $y/x$  with respect to  $x$  would be  $-y/x^2$ . So, we just get it simplifying it we get it as  $-y/r^3$ , similarly the derivative of  $\theta$  with respect to  $y$  would be  $x/r^3$ .

Now, we move to the second derivatives, that is  $r_{xx}$  this is same as  $\frac{\partial^2 r}{\partial x^2}$ . Differentiating it again with respect to  $x$ , so what we would get  $1/r$  then we would be getting is  $x$  times the derivative of  $1/r$  that is  $-1/r^2$  into the derivative of  $r$  with respect to  $x$  is  $x/r$ , so we would be getting is  $1/r - x^2/r^3$ .

Similarly, the second derivative with respect to  $y$  that is differentiating  $r_y$  with respect to  $y$  ones more we will get in a similar manner as  $1/r - y^2/r^3$ . Then differentiating  $\theta_x$  with respect to  $x$  1 once more  $y$  is constant with respect to  $x$   $1/r$  its derivative is  $-x/r^2$  so we would get  $\theta_{xx}$  as  $-2xy/r^4$  in similar manner  $\theta_{yy}$  is equal to  $2xy/r^4$ .

(Refer Slide Time: 15:22)

Using chain rule  $u_x = u_r r_x + u_\theta \theta_x$

$$\begin{aligned} \therefore u_{xx} &= (u_r r_x)_x + (u_\theta \theta_x)_x \\ &= (u_r)_x r_x + u_r r_{xx} + (u_\theta)_x \theta_x + u_\theta \theta_{xx} \\ &= (u_{rr} r_x + u_{r\theta} \theta_x) r_x + u_r r_{xx} + (u_{r\theta} r_x + u_{\theta\theta} \theta_x) \theta_x + u_\theta \theta_{xx} \end{aligned}$$

$u_y = u_r r_y + u_\theta \theta_y$

$$\begin{aligned} \therefore u_{yy} &= (u_r r_y)_y + (u_\theta \theta_y)_y \\ &= (u_r)_y r_y + u_r r_{yy} + (u_\theta)_y \theta_y + u_\theta \theta_{yy} \\ &= (u_{ry} r_y + u_{r\theta} \theta_y) r_y + u_r r_{yy} + (u_{r\theta} r_y + u_{\theta\theta} \theta_y) \theta_y + u_\theta \theta_{yy} \end{aligned}$$

So now, we will find out the derivatives with respect to x and y and z change it to the derivative with respect to r and theta using the chain rule. We do know that  $u_x$  can be written as  $u_r$  into  $r_x$  plus  $u_\theta$  into  $\theta_x$ .

Now, again differentiating it with respect to x, we can write  $u_{xx}$  as  $u_r r_x$  differentiated with respect to x plus  $u_\theta \theta_x$  differentiated with respect to x. So, this subscript I am using for the derivative other than writing this  $\frac{\partial}{\partial x}$  I am using this subscript x.

So, now, if I differentiate this is the product of two functions one is the  $\frac{\partial u}{\partial r}$  and the other is  $\frac{\partial r}{\partial x}$ . So, we do get it this one as the derivative of  $u_r$  with respect to x into  $r_x$  plus  $u_r$  into the derivative of  $r_x$  with respect to x that is the second derivative of r with respect to x  $r_{xx}$ , in a similar manner  $u_\theta$  the derivative of this with respect to x times  $\theta_x$  plus  $u_\theta$  times  $\theta_{xx}$ . Now, for  $u_r$  differentiating it with respect to x, we do again use the chain rule what we would get, the derivative of  $u_r$  with respect to r that is the second derivative of u with respect to r  $u_{rr}$  into  $r_x$  plus  $u_r$  theta into  $\theta_x$  this  $r_x$  is as such this term is as such  $u_r$  times  $r_{xx}$ .

Then, the derivative of  $u_\theta$  with respect to x again use the chain rule over here, the derivative with respect to r of  $u_\theta$  that we would say is  $\frac{\partial^2 u}{\partial r \partial \theta}$ . So,  $u_r \theta_x$  times  $r_x$  plus  $u_\theta \theta_x$  times  $\theta_x$  that is the second derivative of u with respect to theta into  $\theta_x$  and then this term  $u_\theta$  plus  $\theta_{xx}$  is as such.

Similarly, we could get the  $u_y$  also as using the chain rule  $u_r$  times  $r_y$  plus  $u_\theta$  times  $\theta_y$ , again differentiated with respect to  $y$  in a similar manner. We could write  $u_{ry}$  times derivative with respect to  $y$  and the derivative of  $u_\theta$  and  $\theta_y$  with respect to  $y$ .

Again, use the multiplication rule of the differentiation we do get it the derivative of  $u_r$  with respect to  $y$  into  $r_y$  plus  $u_r$  times the derivative of  $r_y$  with respect to  $y$  that is  $r_{yy}$  this similar manner the derivative of  $u_\theta$  with respect to  $y$  times  $\theta_y$  plus  $u_\theta$  times  $\theta_{yy}$ .

Again, use this chain rule using the derivative of  $u_r$  with respect to  $y$ , we do get it as  $u_{ry}$ ,  $r_{yy}$  plus  $u_r \theta_y \theta_{yy}$  into  $r_y$  plus this term as such  $u_{ry}$ . And for this again using the chain rule  $u_r \theta_y r_{yy}$  plus  $u_\theta \theta_{yy} \theta_y$  times  $\theta_y$  and this term  $u_\theta \theta_{yy}$  as such.

(Refer Slide Time: 18:26)

$$\begin{aligned}
 r_x &= \frac{x}{r}, r_y = \frac{y}{r}, \theta_x = -\frac{y}{r}, \theta_y = \frac{x}{r} \\
 r_{xx} &= \frac{1}{r} - \frac{x^2}{r^3}, r_{yy} = \frac{1}{r} - \frac{y^2}{r^3}, \theta_{xx} = \frac{2xy}{r^4}, \theta_{yy} = \frac{-2xy}{r^4} \\
 u_{xx} &= (u_{rr}r_x + u_{r\theta}\theta_x)r_x + u_r r_{xx} + (u_{r\theta}r_x + u_{\theta\theta}\theta_x)\theta_x + u_\theta \theta_{xx} \\
 u_{xx} &= \frac{x^2}{r^2}u_{rr} - \frac{2xy}{r^3}u_{r\theta} + \frac{y^2}{r^4}u_{\theta\theta} + \left(\frac{1}{r} - \frac{x^2}{r^3}\right)u_r + \frac{2xy}{r^4}u_\theta \\
 u_{yy} &= (u_{rr}r_y + u_{r\theta}\theta_y)r_y + u_r r_{yy} + (u_{r\theta}r_y + u_{\theta\theta}\theta_y)\theta_y + u_\theta \theta_{yy} \\
 u_{yy} &= \frac{y^2}{r^2}u_{rr} + \frac{2xy}{r^3}u_{r\theta} + \frac{x^2}{r^4}u_{\theta\theta} + \left(\frac{1}{r} - \frac{y^2}{r^3}\right)u_r - \frac{2xy}{r^4}u_\theta \\
 \therefore u_{xx} + u_{yy} &= u_{rr} + \frac{1}{r^2}u_{\theta\theta} + \frac{1}{r}u_r
 \end{aligned}$$

So, now, we substitute this  $r_\theta$ ,  $r_x$ ,  $r_y$ ,  $\theta_x$ ,  $\theta_y$  in this what we have obtained, we had obtained this  $r_{xx}$ ,  $r_{yy}$ ,  $\theta_{xx}$  and  $\theta_{yy}$ , moreover we had also obtained  $r_{xy}$ ,  $\theta_{xy}$ ,  $\theta_{xx}$  and  $\theta_{yy}$ .

So, let us first find out  $u_{xx}$  where  $u_{xx}$  just now we had obtained as this formulation  $u_{rr}$ ,  $r_x$  plus  $u_r \theta_x$ ,  $\theta_x$  times  $r_x$  plus  $u_r r_{xx}$  plus  $u_r \theta_x$  plus  $u_\theta \theta_{xx}$  plus  $u_\theta \theta_{xx}$  plus  $u_\theta \theta_{xx}$  now substitute all these. Here, what we would

get is,  $r$  since  $x$  by  $r$ , so I would be getting is the co-efficient of  $u r r$  is  $r x$  square that is  $x$  square upon  $r$  square. So, we would get  $x$  square upon  $r$  square times  $u r r$  co-efficient of  $u r$  theta.

We have used one thing that is the partial derivatives that is the function is continuous in such a manner that where we take the derivative  $u r$  theta or  $u$  theta  $r$  they are same. So, the multiple the co-efficient of  $u r$  theta is  $\theta x r$  here and from here it is  $r x$  theta  $x r$  is  $x$  by  $r$  and  $\theta x$  is minus  $y$  by  $r$ . So, we would be getting is minus  $x y$  upon  $r$  square and we would be getting it 2 times. So, we are getting it minus  $2 xy$  upon  $r$  square  $u r$  theta plus  $y$  square upon  $r$  to the power 4  $u$  theta theta plus 1 by  $r$  minus  $x$  square upon  $r$  cube times  $u r$  that is  $u r r x x$  and then  $u$  theta theta  $x x$  theta  $xx$  is  $2 x y$  upon  $r$  to the power 4  $u$  theta.

Similarly, we can get  $u y y$  again substituting this  $r y r y$  is  $y$  upon  $r$  multiplication of this we would be getting is  $y$  square upon  $r$  square  $u r r$ . And then the co-efficient of  $u r$  theta is  $\theta y r y$  and  $\theta y r y$  from here  $\theta y$  and  $r y$  we would be getting as again  $x y$  upon  $r$  cube that is  $u r$  theta twice with the plus sign now. And, the co-efficient of  $u$  theta theta here would be  $x$  square upon  $r$  square that is we are getting is  $\theta y$  whole square. And then  $u r$  as 1 upon co-efficient of  $u r$  as 1 upon  $r$  minus  $y$  square upon  $r$  cube minus the co-efficient of  $u$  theta is minus  $2 x y$  upon  $r$  4 that is  $\theta y y$  is minus  $2 x y$  upon  $r$  4.

So, now  $u xx$  plus  $u y y$ , what we would get from here? We would get  $x$  square upon  $r$  square plus  $y$  square upon  $r$  square and if you remember  $r$  was nothing, but square root of  $x$  square plus  $y$  square. So,  $x$  square plus  $y$  square upon  $r$  square that is 1, similarly this term would get cancel it out here what we would be getting  $x$  square plus  $y$  square  $r$  is square, so 1 upon  $r$  square.

And, this term we would be getting as 1 upon  $r$  1 upon  $r$  2 upon  $r$  and then with the minus sign  $x$  square plus  $y$  square upon  $r$  cube. Again, what we would be getting a is  $x$  square plus  $y$  square is  $r$  square, so again you would be getting is 1 upon  $r$  and this term will get cancel it out. So, finally, we would get  $u r r$  plus 1 upon  $r$  square times  $u$  theta theta plus 1 upon  $r$   $u r$ .

(Refer Slide Time: 22:05)

**Laplace Equation**

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$

$$u_{rr} + \frac{1}{r^2} u_{\theta\theta} + \frac{1}{r} u_r + u_{zz} = 0$$

**Laplace Equation in Cylindrical Coordinates**

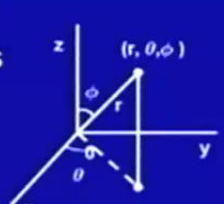

Now, so what will be our Laplace equation, in the cylindrical co-ordinate Laplace equation is this one we have changed only using this x and y, since z was totally independent same as the third co-ordinate over here. So, we would use simply u z z for this 1, so what we would be getting is the changed co-ordinate for x and y we have changed to r and theta we do get it u r r plus 1 upon r square u theta theta plus 1 upon r u r plus u z z is equal to 0, so this is our Laplace equation in cylindrical co-ordinates.

(Refer Slide Time: 22:46)

**Laplace Equation in Spherical Coordinates**

$$\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2} + \frac{\partial^2 u}{\partial z^2} = 0$$

**Spherical Coordinates**

$x = r \cos\theta \sin\phi$ ,  $y = r \sin\theta \sin\phi$ ,  $z = r \cos\theta$

$$r = \sqrt{x^2 + y^2 + z^2}, \theta = \tan^{-1}(y/x), \phi = \tan^{-1} \frac{\sqrt{x^2 + y^2}}{z}$$

$$\Rightarrow r_x = \frac{x}{r}, r_y = \frac{y}{r}, r_z = \frac{z}{r}$$

$$r_{xx} = \frac{1}{r} - \frac{x^2}{r^3}, r_{yy} = \frac{1}{r} - \frac{y^2}{r^3}, r_{zz} = \frac{1}{r} - \frac{z^2}{r^3}$$

Will learn about how to solve these equations, but before that will move to the another co-ordinates that is if my surface is having spherical symmetry that is we change the Laplace equation in spherical co-ordinates, what are these spherical co-ordinates? We do have this is the Laplace equation, this we have to change into the spherical co-ordinates.

Now, what are the spherical co-ordinates if you do remember sphere, we are having all the around in the cylinder we were have is one was one dimensional was exactly same as the Cartesian one, but here we are having is all the round. So, we would talk about these co-ordinates in the all round shape. So, what we are having is in Cartesian co-ordinates this point would be simply called as  $x$   $y$   $z$  plane, we are having is that the distance  $z$  of this point from the origin in the from parallel to the  $z$  axis parallel to the  $x$  axis and parallel to  $y$  axis that is what we are calling  $x$   $y$   $z$ .

Now see, because it is a sphere, so what we would say is we trying the origin? Origin is being trying to this point. So, now, this is do not take it this is not in the  $x$   $y$  plane this is now in the three dimensional one. So, origin is been trying to this one, this is what we are saying as the distance between the origin and this point that we are calling  $r$ , so this is  $r$ .

Then, this distance the line which is joining the origin to this one this is making one angle  $\phi$  with respect to the  $z$  axis that is, what we are calling  $\phi$  and as usual if I make it is a perpendicular drop on the  $x$   $y$  plane I will get this point. So, this point in the polar co ordinates we do have that this distance we are calling  $r$  and this angle we are calling  $\theta$ .

So, now,  $r$  I am not taking and  $r$  we are taking is the distance of this point from the in this three dimensional displace from the origin and  $\theta$  is that angle which would make a  $\phi$  drop apart from the that is  $\phi$  takes its image in the  $x$   $y$  plane. Then this angle with this line would be making that is the line joining the origin to this point in the  $x$   $y$  plane, this line with the angle it is making this is called  $\theta$ .

Because, while we are taking it one since we are talking about the sphere its cross section would be any circle, whatever be the polar co-ordinates for the circle we do have  $r$  and  $\theta$ , but that  $r$  we are leaving because that  $r$  we could find it out using this  $r$  that is in the three dimensional distance from origin to the point and the surface of the sphere.

So, if I just make it out we do know that from this point if we are talking about then  $x$  is the distance from here to here. So, first let us try to make that is that we would be getting it in the terms of  $r$  and  $\phi$ , so we would get it as  $r$  this distance would be  $r \cos \phi$  this would be  $r \sin \phi$ , because  $\phi$  is the angle on this side of the  $z$  axis. So, this distance this distance would be  $r \sin \phi$  and this distance would be  $r \cos \phi$ .

So, we have got that  $z$  is  $r \cos \phi$ , now what would be  $x$  and  $y$   $x$  and  $y$ , now we are getting as this distance that is what I said is other requirement this is because this distance is nothing but  $r \sin \phi$  if this is  $r \sin \phi$  and this is the angle  $\theta$ . We do know this next called this distance as  $\rho$ .

Then, we do know that  $x$  is  $\rho \cos \theta$  and  $y$  is  $\rho \sin \theta$  now what is  $\rho$ ,  $\rho$  is  $r \sin \phi$ . So, we have got  $x$  as  $r \cos \theta \sin \phi$  or rather we could say is now my this  $\rho$  is  $r \cos \theta \sin \phi$  multiply with  $\cos \theta$ , but I have written in this manner because we are writing it  $r \theta \phi$ . So,  $r \cos \theta \sin \phi$   $y$  is  $r \sin \theta \sin \phi$  and  $z$  is  $r \cos \phi$ .

Now, again if you have to change it, to these new co-ordinates that is in the new variables  $r$   $\theta$  and  $\phi$  we would use this relationship. So, again we would require to change it to in the  $r$   $\theta$  and  $\phi$ , so we require those relations. So, let see  $r$  would be now square root of  $x^2 + y^2 + z^2$  that is the distance from origin to this point  $x$   $y$   $z$   $\theta$  as I said would be  $\tan^{-1} \frac{y}{x}$   $\phi$  is.

Now, the angle from here we would find it out that is we do get it  $x^2 + y^2$  would be  $r^2 \sin^2 \phi$ , square root of  $x^2 + y^2$  would be  $r \sin \phi$  and  $z$  is  $r \cos \phi$ . So, we would get  $\phi$  as  $\tan^{-1} \frac{\sqrt{x^2 + y^2}}{z}$ , find out the derivative of  $r$   $\theta$  and  $\phi$  with respect to  $x$   $y$  and  $z$  and the second derivative that we would be requiring.

So, first the derivative of  $r$  with respect to  $x$   $y$  and  $z$ , if I differentiate it as in the first manner we had seen here also we would get it as  $\frac{x}{r}$ ,  $\frac{y}{r}$  that is the derivative with respect to  $y$  as  $\frac{y}{r}$ ,  $\frac{z}{r}$  as the derivative with respect to  $z$  as  $\frac{z}{r}$ . From here, if I just go with the second derivative again with respect to  $x$ . So, I will get  $\frac{1}{r} - \frac{x^2}{r^3}$  and the derivative of  $r$  with respect to  $x$  is  $\frac{x}{r}$ , so again we would get  $\frac{1}{r} - \frac{x^2}{r^3}$ .

Similarly, the second derivative of  $r$  with respect to  $y$  is  $1$  upon  $r$  minus  $y$  square upon  $r$  cube and the third derivative second derivative with respect to  $z$  that is  $r z z$  would be  $1$  upon  $r$  minus  $z$  square upon  $r$  cube.

(Refer Slide Time: 29:02)

$$r = \sqrt{x^2 + y^2 + z^2}, \theta = \tan^{-1}(y/x), \phi = \tan^{-1} \frac{\sqrt{x^2 + y^2}}{z}$$

$$\theta_x = -\frac{y}{x^2 + y^2}, \theta_y = \frac{x}{x^2 + y^2}, \theta_z = 0$$

$$\theta_{xx} = \frac{2xy}{(x^2 + y^2)^2}, \theta_{yy} = \frac{-2xy}{(x^2 + y^2)^2}, \theta_{zz} = 0$$

$$\phi_x = \frac{xz}{r^2 \sqrt{x^2 + y^2}}, \phi_y = \frac{yz}{r^2 \sqrt{x^2 + y^2}}, \phi_z = -\frac{\sqrt{x^2 + y^2}}{r^2}$$

Now, since this  $r$  is this one now let us come to the derivative of theta with respect to  $x$   $y$  and  $z$ . Now, we see is that theta is a function of  $y$  and  $x$  only its derivative with respect to  $z$  would be  $0$ .

So, theta  $x$  that is the derivative of  $x$  with respect to theta with respect to  $x$  as in the previous one we had obtained, there we had written alpha, but now this  $r$  is having  $x$  square plus  $y$  square plus  $z$  square. We would get minus  $y$  upon  $x$  square plus  $y$  square theta  $y$  as  $x$  upon  $x$  square plus  $y$  square and since it is not containing any term of  $z$ , we will get theta  $z$  is equal to  $0$ .

So, the second derivatives theta  $x x$  we would get it as  $2 x y$  upon  $x$  square plus  $y$  square the whole square because its derivative would be minus  $1$  upon  $x$  square plus  $y$  square and the derivative of this would be  $2 x$ . So, we would be getting like this one, similarly for theta  $y$  we would be getting it minus  $2 x y$  upon  $x$  square plus  $y$  square whole square and the second derivative with respect to  $z$  again it would be  $0$ .

Now come to this phi, its derivative with respect to x tan inverse x does have its derivative 1 upon x square 1 upon 1 plus x square, and then this is the function of x y and z that we will define.

(Refer Slide Time: 30:29)

Using chain rule  $u_x = u_r r_x + u_\theta \theta_x + u_\phi \phi_x$

$$\begin{aligned} \therefore u_{xx} &= (u_r r_x)_x + (u_\theta \theta_x)_x + (u_\phi \phi_x)_x \\ &= (u_r)_x r_x + u_r r_{xx} + (u_\theta)_x \theta_x + u_\theta \theta_{xx} + (u_\phi)_x \phi_x + u_\phi \phi_{xx} \\ &= (u_{rr} r_x + u_{r\theta} \theta_x + u_{r\phi} \phi_x) r_x + u_r r_{xx} \\ &\quad + (u_{r\theta} r_x + u_{\theta\theta} \theta_x + u_{\theta\phi} \phi_x) \theta_x + u_\theta \theta_{xx} \\ &\quad + (u_{r\phi} r_x + u_{\theta\phi} \theta_x + u_{\phi\phi} \phi_x) \phi_x + u_\phi \phi_{xx} \end{aligned}$$

See using chain rule  $u_x$  can be written as  $u_r r_x$  plus  $u_\theta \theta_x$  plus  $u_\phi \phi_x$ , now what are you seeing is that is I have extended that chain rule to the three variables now. The variables are that is  $u$  is the function of  $x$   $y$  and  $z$  and we are changing this  $x$  to function of  $r$   $\theta$  and  $\phi$ , so we have to apply these three various rule. Again, if I have to find out the second derivative with respect to  $x$  using similar manner we could write it out that is the derivative of  $u_r r_x$  with respect to  $x$   $u_\theta \theta_x$  with respect to  $x$  and  $u_\phi \phi_x$  with respect to  $x$ .

Using the product rule, we could write it as the derivative of  $u_r$  with respect to  $x$  into  $r_x$  plus  $u_r r_{xx}$  plus  $u_\theta$  derivative with respect to  $x$  into  $\theta_x$  and then  $u_\theta$  the derivative of  $\theta_x$  with respect to  $x$  that is  $\theta_{xx}$ . Similarly, the derivative of  $u_\phi$  with respect to  $x$  multiplied with  $\phi_x$  and then  $u_\phi$  the derivative of  $\phi_x$  with respect to  $x$  that is  $\phi_{xx}$ .

Again, for finding out the derivative of  $u_r$  with respect to  $x$  again we will use the chain rule and that says is we would be getting as the derivative of  $u_r$  with respect to  $r$  that is  $u_{rr} r_x$  plus  $u_r \theta_x$  plus  $u_r \phi_x$ . Now, you see as again using the, that is the

derivatives the order of the differentiation can be interchanged then this term  $u_{rrx}$  has been as such.

Then, using the chain rule again for the derivative of  $u_\theta$  with respect to  $x$ , we get it  $u_{r\theta} r_x$  plus  $u_{\theta\theta} \theta_x$  plus  $u_{\theta\phi} \phi_x$  times  $\theta_x$  and this  $u_{\theta\theta} \theta_x$  as such. Then using the chain rule, again for  $u_\phi$  the derivative of  $u_\phi$  with respect to  $x$  we get  $u_{r\phi} r_x$  plus  $u_{\theta\phi} \theta_x$  plus  $u_{\phi\phi} \phi_x$  times  $\phi_x$  plus  $u_{\phi\theta} \theta_x$ .

(Refer Slide Time: 32:41)

$$\begin{aligned}
 u_{xx} = & \frac{x^2}{r^2} u_{rr} - \frac{2xy}{r(x^2+y^2)} u_{r\theta} + \frac{2x^2z}{r^3 \sqrt{x^2+y^2}} u_{r\phi} \\
 & - \frac{2xyz}{r^2 (x^2+y^2)^{3/2}} u_{\theta\phi} + \frac{y^2}{(x^2+y^2)^2} u_{\theta\theta} + \frac{x^2y^2}{r^4 (x^2+y^2)} u_{\phi\phi} \\
 & + \left( \frac{1}{r} - \frac{x^2}{r^3} \right) u_r + \frac{2xy}{(x^2+y^2)^2} u_\theta \\
 & + \left( \frac{y^2z}{r^3 (x^2+y^2)^{3/2}} - \frac{2x^2z}{r^4 \sqrt{x^2+y^2}} \right) u_\phi
 \end{aligned}$$

So, this is what you have got  $u_{xx}$  in a similar manner, we can use the chain rule. So,  $u_{xx}$  we could now substitute the values of that  $r_x$  and  $r_{xx}$  and all those things, so we do get is now you can see it in your calculation yourself, you would be getting is  $x^2$  upon  $r^2$  minus  $2xy$  upon  $r$  times  $x^2 + y^2$  times  $u_{r\theta}$  plus  $2x^2z$  upon  $r^3$  square root of  $x^2 + y^2$  times  $u_{r\phi}$  minus  $2xyz$  upon  $r^2$  times  $(x^2 + y^2)^{3/2}$  times  $u_{\theta\phi}$  plus  $y^2$  upon  $(x^2 + y^2)^2$  times  $u_{\theta\theta}$  plus  $x^2y^2$  upon  $r^4$  times  $(x^2 + y^2)$  times  $u_{\phi\phi}$  plus  $\left( \frac{1}{r} - \frac{x^2}{r^3} \right) u_r$  plus  $\frac{2xy}{(x^2 + y^2)^2} u_\theta$  plus  $\left( \frac{y^2z}{r^3 (x^2 + y^2)^{3/2}} - \frac{2x^2z}{r^4 \sqrt{x^2 + y^2}} \right) u_\phi$ .

Plus  $\frac{1}{r} - \frac{x^2}{r^3}$  times  $u_r$  plus  $\frac{2xy}{(x^2 + y^2)^2} u_\theta$ . And then we would be getting is that  $\phi_{xx}$  times  $u_\phi$ , so  $y^2z$  upon  $r^3$  times  $(x^2 + y^2)^{3/2}$  minus  $2x^2z$  upon  $r^4$  times square root of  $x^2 + y^2$ .

times  $u_\phi$ . All these we had already calculated, so we had substituted finally  $u_{xx}$  we have this in our expression.

(Refer Slide Time: 34:12)

Using chain rule  $u_y = u_r r_y + u_\theta \theta_y + u_\phi \phi_y$

$$\therefore u_{yy} = (u_r r_y)_y + (u_\theta \theta_y)_y + (u_\phi \phi_y)_y$$

$$= (u_r)_y r_y + u_r r_{yy} + (u_\theta)_y \theta_y + u_\theta \theta_{yy} + (u_\phi)_y \phi_y + u_\phi \phi_{yy}$$

$$= (u_{rr} r_y + u_{r\theta} \theta_y + u_{r\phi} \phi_y) r_y + u_r r_{yy} + (u_{r\theta} r_y + u_{\theta r} \theta_y + u_{\theta\phi} \phi_y) \theta_y + u_\theta \theta_{yy} + (u_{r\phi} r_y + u_{\theta\phi} \theta_y + u_{\phi r} \phi_y) \phi_y + u_\phi \phi_{yy}$$

Similarly, we can get using the chain rule  $u_y$  as  $u_r r_y + u_\theta \theta_y + u_\phi \phi_y$ , and then second derivative again using similarly that is first using the chain rule. Then using the multiplication rule  $u_r y r_y + u_r r_y y$  and so on, we could get it in a similar manner. Again using the chain rule for  $u_r$  the derivative of  $u_r$  with respect to  $y$  derivative of  $u_\theta$  with respect to  $y$  and the derivative of  $u_\phi$  with respect to  $y$  we would again use the chain rule and we do get final is as  $u_{rr} r_y + u_r \theta_y + u_r \phi_y + u_r r_{yy} + u_\theta r_y + u_\theta \theta_y + u_\theta \phi_y + u_\theta \theta_{yy} + u_\theta \phi_y + u_\phi r_y + u_\phi \theta_y + u_\phi \phi_y + u_\phi \phi_{yy}$ .

And then  $u_r$  times  $r_y y$  as such, similarly, for this  $u_\theta$  we could write  $u_\theta$  with respect to  $y$   $u_r \theta_y r_y + u_\theta \theta_y \theta_y + u_\theta \phi_y \phi_y + u_\theta \theta_{yy} + u_\theta \phi_{yy}$  as such. Then again using the chain rule for the derivative of  $u_\phi$  with respect to  $y$   $u_r \phi_y r_y + u_\theta \phi_y \theta_y + u_\phi \phi_y \phi_y + u_\phi \phi_{yy}$  into  $\phi_y$  and  $u_\phi \phi_y y$  as such again we have seen is we are using this as the order of differentiation is not making a difference in our calculations.

Now, again we had already calculated what is the coefficient of  $u_r r_y$  from here we would get  $r_x r_y$  whole square. The coefficient of  $u_r \theta_y$  we would be getting from here  $\theta_y r_y$  and from here again  $r_y \theta_y$ , so we would get 2 times  $r_y \theta_y$ , similarly for  $u_r \phi_y r_y \phi_y$  and from here again  $r_y \phi_y$  that is 2 times  $r_y \phi_y$ .

Similarly, we can get  $\phi_u \phi_\theta$  from here and  $u_\phi \theta$  from here,  $\theta_\phi$  from here as  $\phi_y \theta_y$   $\phi_y \theta_y$ .

And, the co-efficient of  $u_\theta \theta$  would be  $\theta_y$  times  $\theta_y$  that is  $\theta_y$  the whole square co-efficient of  $u_\phi \phi$  would be  $\phi_y$  the whole square. And then we would be having this that co-efficient of  $u_r$  as  $r_y$  y co-efficient of  $u_\theta$  as  $\theta_y$  y and co-efficient of  $u_\phi$  as  $\phi_y$  y, so now substituting all these knowing all these, because you have already calculated  $r_x r_y$   $r_y \theta_y$   $\theta_y \phi_y$  and so on.

(Refer Slide Time: 36:42)

$$\begin{aligned}
 u_{yy} = & \frac{y^2}{r^2} u_{\phi\phi} + \frac{2xy}{r(x^2+y^2)} u_{r\theta} + \frac{2y^2z}{r^3 \sqrt{x^2+y^2}} u_{r\phi} \\
 & + \frac{2xyz}{r^2(x^2+y^2)^{3/2}} u_{\theta\phi} + \frac{x^2}{(x^2+y^2)^2} u_{\theta\theta} + \frac{y^2z^2}{r^4(x^2+y^2)} u_{\phi\phi} \\
 & + \left( \frac{1}{r} - \frac{y^2}{r^3} \right) u_r - \frac{2xy}{(x^2+y^2)^2} u_\theta \\
 & + \left( \frac{x^2z}{r^3(x^2+y^2)^{3/2}} - \frac{2y^2z}{r^4 \sqrt{x^2+y^2}} \right) u_\phi
 \end{aligned}$$

We do get it finally, as  $y^2$  upon  $r^2$   $u_{\phi\phi}$  plus  $2xy$  upon  $r$  times  $x^2+y^2$  plus  $2y^2z$  upon  $r^3$  times the square root of  $x^2+y^2$   $u_{r\phi}$ . Plus  $2xyz$  upon  $r^2$  times  $x^2+y^2$  to the power 3 by 2  $u_{\theta\phi}$  plus  $x^2$  upon  $(x^2+y^2)^2$   $u_{\theta\theta}$  plus  $y^2z^2$  upon  $r^4$  times  $x^2+y^2$  into  $u_{\phi\phi}$ . Plus  $\left( \frac{1}{r} - \frac{y^2}{r^3} \right) u_r - \frac{2xy}{(x^2+y^2)^2} u_\theta + \left( \frac{x^2z}{r^3(x^2+y^2)^{3/2}} - \frac{2y^2z}{r^4 \sqrt{x^2+y^2}} \right) u_\phi$ .

And then the comes  $u_r u_\theta$  and  $u_\phi$  1 upon  $r$  minus  $y^2$  upon  $r^3$  times  $u_r$  minus  $2xy$  upon  $(x^2+y^2)^2$  times  $u_\theta$  and  $x^2z$  upon  $r^3$  times  $(x^2+y^2)^{3/2}$  minus  $2y^2z$  upon  $r^4$  times square root of  $x^2+y^2$  times  $u_\phi$ .

(Refer Slide Time: 37:47)

Using chain rule  $u_z = u_r r_z + u_\theta \theta_z + u_\phi \phi_z$

$$\therefore u_{zz} = (u_r r_z)_z + (u_\theta \theta_z)_z + (u_\phi \phi_z)_z$$

$$= (u_r)_z r_z + u_r r_{zz} + (u_\theta)_z \theta_z + u_\theta \theta_{zz} + (u_\phi)_z \phi_z + u_\phi \phi_{zz}$$

$$= (u_{rr} r_z + u_{r\theta} \theta_z + u_{r\phi} \phi_z) r_z + u_r r_{zz}$$

$$+ (u_{r\theta} r_z + u_{\theta\theta} \theta_z + u_{\theta\phi} \phi_z) \theta_z + u_\theta \theta_{zz}$$

$$+ (u_{r\phi} r_z + u_{\theta\phi} \theta_z + u_{\phi\phi} \phi_z) \phi_z + u_\phi \phi_{zz}$$

$$\therefore u_{zz} = (u_{rr} r_z + u_{r\theta} \theta_z + u_{r\phi} \phi_z) r_z + u_r r_{zz}$$

$$+ (u_{r\phi} r_z + u_{\theta\phi} \theta_z + u_{\phi\phi} \phi_z) \phi_z + u_\phi \phi_{zz}$$

Similarly, for  $u_z$  again we use the same kind of chain rule  $u_r r_z + u_\theta \theta_z + u_\phi \phi_z$ , the second derivative again first using this chain rule that is differentiation of the sum same as the sum of the differentiations. And then using the product rule for the differentiation as that is the derivative of first function into the second function plus the first function into the derivative of the second function like that. Again using in this, the derivative of  $u_r$  with respect to  $z$  and  $u_\theta$  with respect to  $z$  and  $u_\phi$  with respect to  $z$ , again using the chain rule for this we would get it finally, as  $u_{rr} r_z + u_r r_{zz} + u_{r\theta} \theta_z + u_\theta \theta_{zz} + u_{r\phi} \phi_z + u_\phi \phi_{zz}$ .

And then the chain rule over here would give me  $u_r \theta_z r_z + u_\theta \theta_z \theta_z + u_\theta \phi_z \phi_z$  plus  $u_\theta \theta_z \theta_z$  and the third one the  $u_\phi r_z + u_\theta \phi_z \theta_z + u_\phi \phi_z \phi_z$  into  $\phi_z$  plus  $u_\phi \phi_z \phi_z$ . Then, you see we have got that is our  $\theta$  was the function of  $x$  and  $y$  only, it was not having any  $z$  it is not a function of  $z$ , so  $\theta_z$  derivative of  $\theta$  with respect to  $z$  or the second derivative of  $\theta$  with respect to  $z$  they are 0, that is this middle term goes out this is simply 0. And here also, this term we would get is this term would go to 0, so finally, we would be getting as  $u_{rr} r_z + u_r r_{zz} + u_{r\phi} \phi_z + u_\phi \phi_{zz}$  again this term will also be 0. So, finally, we would be getting is  $u_{rr} r_z + u_r r_{zz} + u_{r\phi} \phi_z + u_\phi \phi_{zz}$  plus  $u_r \phi_z \phi_z + u_r \theta_z \theta_z$  and then this third term  $u_r \phi_z \theta_z$  and  $u_\theta \phi_z \phi_z$  times  $\phi_z$  and  $u_\phi \phi_z \phi_z$  this term will also go out.

So, now the co-efficient of  $u_{rr}$  is nothing but  $r^2$  whole square co-efficient of  $u_{r\theta}$  from here is, this  $\theta$  is not the point this is 0 the co-efficient of  $u_{r\phi}$  from here is  $\phi$   $z$   $r$   $z$  and the co-efficient of  $u_{r\phi}$  is here some here is also  $r$   $z$   $\phi$   $z$ . And then the co-efficient of  $u_{\phi\phi}$  is  $\phi$   $z$  square and  $u_{r\phi}$  co-efficient is  $r$   $z$   $z$  and  $u_{\phi\phi}$  co-efficient is  $\phi$   $z$   $z$ .

(Refer Slide Time: 40:23)

$$u_{zz} = \frac{z^2}{r^2} u_{rr} - \frac{2z\sqrt{x^2+y^2}}{r^3} u_{r\phi} + \frac{x^2+y^2}{r^4} u_{\phi\phi} + \left( \frac{1}{r} - \frac{z^2}{r^3} \right) u_r + \frac{2z\sqrt{x^2+y^2}}{r^4} u_\phi$$

Hence Laplace Equation in spherical Coordinates

$$u_{rr} + \frac{1}{r^2 \sin^2 \phi} u_{\theta\theta} + \frac{1}{r^2} u_{\phi\phi} + \frac{2}{r} u_r + \frac{\cot \phi}{r^2} u_\phi = 0$$

Substitute it we would finally, get  $z^2$  upon  $r^2$  times  $u_{rr}$  minus  $2z$   $x$  square plus square root of  $x$  square plus  $y$  square upon  $r^3$  times  $u_{r\phi}$  plus  $x$  square plus  $y$  square upon  $r^4$  times  $u_{\phi\phi}$  and the second order derivative. And then  $u_r$  and  $u_\phi$  the co-efficient of that is  $\frac{1}{r} - \frac{z^2}{r^3}$  and  $\frac{2z\sqrt{x^2+y^2}}{r^4}$ , so  $r$   $r$   $z$   $z$  and  $\phi$   $z$   $z$ , so that is  $1$  upon  $r$  minus  $z$  square upon  $r^3$   $u_r$  plus  $2z$  square root of  $x$  square plus  $y$  square upon  $r^4$  times  $u_\phi$ .

So, now we have got  $u_{xx}$   $u_{yy}$  and  $u_{zz}$  in all these terms you see is that is this the co-efficient of  $u_{rr}$  in  $u_{xx}$  was  $x^2$  upon  $r^2$  in  $u_{yy}$  was  $y^2$  upon  $r^2$  and in  $u_{zz}$  it is  $z^2$  upon  $r^2$ . So, if I add up  $u_{xx}$  plus  $u_{yy}$  plus  $u_{zz}$  it would be getting is  $x^2$  plus  $y^2$  plus  $z^2$  divided by  $r^2$ , that is same as 1.

Similarly, we just see is that all those terms we can spread it on one sheet, and then we can see that some of them are canceling it out some of them are being simplified. And finally, what we would get the Laplace equation in spherical co-ordinate as  $u_{rr} + \frac{1}{r^2 \sin^2 \phi} u_{\theta\theta} + \frac{1}{r^2} u_{\phi\phi} + \frac{2}{r} u_r + \frac{\cot \phi}{r^2} u_\phi = 0$

upon  $r^2 \sin^2 \phi$   $u_{\theta\theta}$  plus  $\frac{1}{r^2}$   $u_{\phi\phi}$  plus  $\frac{2}{r}$   $u_r$  plus  $\cot \phi$  upon  $r^2$   $u_\phi$ .

You see, we are having here certain terms in the terms of  $x$ ,  $y$  and  $z$ , what we would do finally, is that is square root of  $x^2 + y^2$  that is  $\sqrt{x^2 + y^2}$  that is nothing but  $r \sin \phi$ , so like that we would be getting. And similarly,  $\tan \phi$  is square root of  $x^2 + y^2$  upon  $z$ , so like that we would be substituting these those terms we would get in this simplified form. Sometimes, it is easy to write this differential equation in another manner also that is much easy for solving the equation what is that alternative for...

**Alternative way for Laplace Equation  
in spherical Coordinates**

$$u_{rr} + \frac{1}{r^2 \sin^2 \phi} u_{\theta\theta} + \frac{1}{r^2} u_{\phi\phi} + \frac{2}{r} u_r + \frac{\cot \phi}{r^2} u_\phi = 0$$

$$\frac{1}{r^2} \left[ u_{rr} + 2r u_r + \frac{1}{\sin \phi} (\sin \phi u_{\theta\theta} + \cos \phi u_\phi) + \frac{1}{\sin^2 \phi} u_{\phi\phi} \right] = 0$$

$$\frac{\partial}{\partial r} \left( r^2 \frac{\partial u}{\partial r} \right) + \frac{1}{\sin \phi} \frac{\partial}{\partial \phi} \left( \sin \phi \frac{\partial u}{\partial \phi} \right) + \frac{1}{\sin^2 \phi} u_{\theta\theta} = 0$$

This is my equation Laplace equation in spherical co-ordinates we have got  $u_{rr}$  plus  $\frac{1}{r^2 \sin^2 \phi} u_{\theta\theta}$  plus  $\frac{1}{r^2} u_{\phi\phi}$  plus  $\frac{2}{r} u_r$  plus  $\cot \phi$  upon  $r^2$   $u_\phi$  is equal to 0. Now, you see here I am having 1 term as  $u_{rr}$  and here I am having is 1 term of  $2$  upon  $r$   $u_r$  and we are having is  $\frac{1}{r^2 \sin^2 \phi} u_{\theta\theta}$  all the times in the deniers except at this point and this point.

So, first we will take  $\frac{1}{r^2}$  outside, if I am taking  $\frac{1}{r^2}$  outside, here I would get  $r^2$  times  $u_{rr}$  and then here I would get  $2$  times  $r$  times  $u_r$ . So, we could simply write it out in that manner  $u_{rr}$  plus  $2r u_r$  that is this term have it in first. Then from here  $\frac{1}{r^2 \sin^2 \phi}$  is common it would be  $\frac{1}{\sin^2 \phi} (u_{\theta\theta} + \frac{\cos \phi}{\sin \phi} u_\phi + u_{\phi\phi}) = 0$

upon  $r^2$  has gone from here also  $\cot \phi$  means we could write it as  $\cos \phi$  upon  $\sin \phi$ . So, again  $1$  upon  $\sin \phi$  from these two terms I would take it out.

If I am taking out this it should be  $1$  upon  $\sin^2 \phi$  why so we would be getting it as  $\sin \phi \cdot u_{\phi\phi} + \cos \phi \cdot u_{\phi} + 1$  upon  $\sin^2 \phi \cdot u_{\theta\theta}$  that is this term as such. So, from here what we are getting is  $1$  upon  $r^2$  is outside  $1$  upon  $\sin \phi$  we have taken outside  $u_{\phi\phi}$  co-efficient I have to multiply  $\sin \phi$  and then I would get  $\cos \phi \cdot u_{\phi}$ , and this  $1$  upon  $r^2 \sin^2 \phi$  times  $u_{\theta\theta}$  that is as such. This is equal to  $0$  this would be my equation.

So, now, because it is equated to  $0$  and  $r^2$  this is the distance, this cannot be we are taking the points, so this is we are not taking it as  $0$ . Some sphere of some radius  $r$ , so the boundary surface we are not taking it any point on the surface that would never give me the distance  $0$ . So, we can take it that side and we would get it simply the equation like this  $1$  what is in the bracket  $1$  that is equated to  $0$ .

So, this one let us take the first two terms we could say is that is if I take the function  $r^2$  times  $\frac{\partial u}{\partial r}$ ,  $u_r$  means  $\frac{\partial u}{\partial r}$  if I differentiate it with respect to  $r$  using the product rule I would get it  $r^2$  times. So, here actually I think forgotten  $r^2$ , so  $r^2$  has to be here. So,  $r^2$  times  $u_r$  and then the derivative of  $r^2$  is  $2r$  and then  $u_r$ . So, this is what you are getting is  $r^2 \frac{\partial u}{\partial r}$ .

Then,  $1$  upon  $\sin \phi$  now here if I see, the function if I take  $\sin \phi \cdot u_{\phi}$  its derivative with respect to  $\phi$  would be  $\sin \phi$  times  $u_{\phi\phi}$ . And then the derivative of  $\sin \phi$  is  $\cos \phi$  and  $\phi$  as such, so it is  $\frac{\partial}{\partial \phi} \sin \phi \cdot \frac{\partial u}{\partial \phi}$  and then the third term is as such. So, this alternative form is many times much easier to solve, so we do also use this alternative form rather in our example we would be using this alternative form.

So, this is what we have changed the, our Laplace equation into either cylindrical co-ordinates or spherical co-ordinates. Let us, try to see is that is, how to find out the solution, so let us first try the surface of the boundary as sphere or spherical symmetry. So, we would use this spherical Laplace equation in spherical co-ordinates.

**Boundary Value Problem in  $z$   
Spherical Coordinates**

Boundary condition on  
a sphere  $S$  of radius  $R$   
 $u(R, \theta, \phi) = f(\phi)$

Electrostatic Potential

$$\frac{\partial}{\partial r} \left( r^2 \frac{\partial u}{\partial r} \right) + \frac{1}{\sin \phi} \frac{\partial}{\partial \phi} \left( \sin \phi \frac{\partial u}{\partial \phi} \right) + \frac{1}{\sin^2 \phi} \frac{\partial^2 u}{\partial \theta^2} = 0$$

Solution  $u(r, \phi)$  independent of  $\theta \quad \therefore u_{\theta\theta} = 0$

$$\frac{\partial}{\partial r} \left( r^2 \frac{\partial u}{\partial r} \right) + \frac{1}{\sin \phi} \frac{\partial}{\partial \phi} \left( \sin \phi \frac{\partial u}{\partial \phi} \right) = 0 \quad \lim_{r \rightarrow \infty} u(r, \phi) = 0$$

For this, let us see the boundary values problem here, how we could define, suppose my region of interest is this ball that is sphere and the boundary is the surface of this sphere, what we have been given if the function  $u$  is independent of theta on this surface that the boundary condition is given independent of this theta on this surface.

So, we want boundary condition on a sphere  $s$  of the radius  $R$  now this radius also we have fixed. We say is  $u(R, \theta, \phi) = f(\phi)$  that is independent of theta that says is if I make this kind of situation is arising in electrostatic potential, where  $R$  and the temperature where this we are talking about that we are taking a ball kind of things and we are talking about the potential is at this or outside this ball.

If I make it independent of theta, what it says is, that I would get my differential equation this laplacian equation would be this is govern by this laplacian equation. So, I have written this laplacian equation that what we have written in second form as here, what it would give me that  $u_{\theta\theta}$  and  $u_{\theta\theta\theta}$  would be 0, that is this term will go out.

And my solution, if it is independent of theta  $u_{\theta\theta}$  would be 0 that says is i would get only two terms  $\frac{\partial}{\partial r} \left( r^2 \frac{\partial u}{\partial r} \right) + \frac{1}{\sin \phi} \frac{\partial}{\partial \phi} \left( \sin \phi \frac{\partial u}{\partial \phi} \right) = 0$ . So, now what we have defined, we have got that is if I am interested to determine the electrostatic potential on a spherical region. I could use it, on that what we have seen is it is independent of the third co-ordinate theta, the solution is independent of third co-ordinate theta. Then my solution would be  $u$

$r$   $\phi$  and the governing equation then would be  $\nabla \cdot (\nabla r^2 \nabla u) = 0$  plus  $1/\sin \phi \nabla \phi \sin \phi \nabla u = 0$ .

One more thing we would like to say is that this potential has to go to 0 as  $r$  approaches to infinity that is we say that on this all those potential all the inside this, because the boundary condition is on the surface. So inside the sphere, and outside the sphere, so inside the sphere the boundary condition will come over here outside this sphere, we do say that is limit as  $r$  approaches to infinity  $u(r, \phi) = 0$ .

So, now, what we are having is we have been defining our boundary condition on the surface that is on the boundary  $S$  the function is been described on the boundary  $S$ . So, this is Dirichlet kind of problem that is the first kind of boundary value problem, that is called the Dirichlet problem. So, let us learn how to solve the Dirichlet boundary value problems. where my differential equation is this and the boundary conditions boundary condition is this one using this one more condition under the limit case. So, we would learn, how to solve this boundary value problem the Dirichlet problem that we would learn in the next lecture.

So, today what we had learnt, we have learnt that is if we have a three dimensional Laplace equation this is some important application partial differential equation which is arising in basically electro statics or in fluid flow and heat flow kind of things, what we had learnt is that is when we are talking about heat flow and fluid flow it is two dimensional Laplace equation which we had learnt little earlier.

Now, we are talking about the electrostatic that is potential and we had learnt that is solution which we are discussing that is how to find out the solution this theory we are calling that is why potential theory. So, today we had made one kind of change if my surface is spherically symmetry or if I am changing my co-ordinates Cartesian co-ordinates to spherical co-ordinates. Then, I would go ahead with the, I am changing the Laplace equation into spherical co-ordinates defining the boundary value problems that is Dirichlet problems the first kind of boundary value problems. So, next class we would our next lecture we would learn how to solve this Dirichlet problem.

Thank you.
