Lecture - 9
Laplace Transformation (Contd.)

Dear viewers, my today's lecture is in continuation to my previous lecture on Laplace Transformation, where in we studied the existence theorem for the Laplace transforms and some of its properties. We will continue that discussion with some more properties of the Laplace transforms.

(Refer Slide Time: 00:53)

**Laplace transforms of
Derivatives and Integrals**

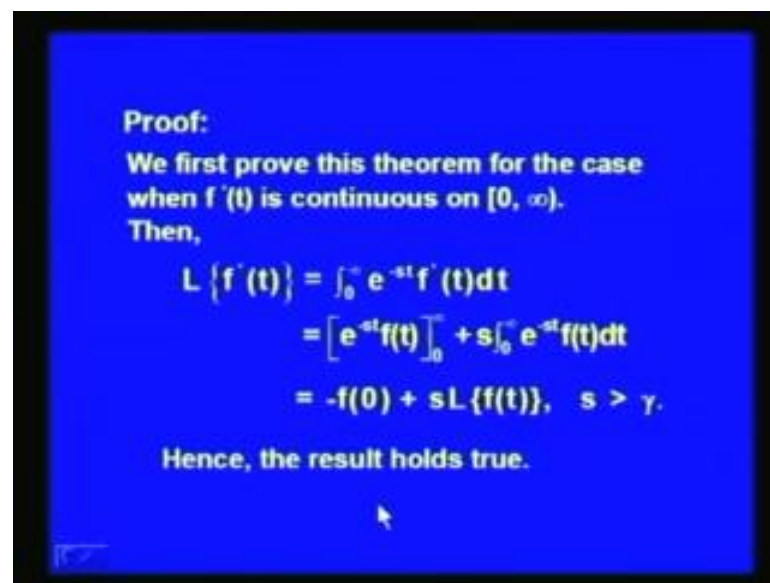

Theorem 1:
Suppose that $f(t)$ is continuous for all $t \geq 0$ and is of exponential order γ on $[0, \infty)$. Further, let $f'(t)$ be piecewise continuous on $[0, \infty)$. Then, $L(f'(t))$ exists and

$$L\{f'(t)\} = sL\{f(t)\} - f(0), \text{ for } s > \gamma.$$

Let us first discuss the Laplace transform of derivative of a function, that the theorem 1 tells us that when we take the Laplace transform of derivative of a function what we get is the Laplace transform of the function multiplied by s that is s into $L\{f(t)\}$ minus $f(0)$. So, this means that when the Laplace transform \mathcal{L} acts on the derivative function, you get the function transform multiplied by s . That means the operation of calculus by acting on when we act by the Laplace transform on the operation of the calculus, what we get is the algebraic operation on the transforms of the function Laplace transforms of the function. So, the operation of calculus is transformed into the algebraic operations on the transforms using the Laplace transformation.

So theorem 1 tells us that, suppose $f(t)$ is continuous function for all t greater than or equal to 0 and is of exponential order γ on the interval 0 to ∞ . Let us recall the definition of exponential order γ , we say that the function $f(t)$ is exponential of exponential order γ provided. We can find constant m greater than 0 such that mod of $f(t)$ is less than or equal to m times e to the power γt for all t greater than or equal to $\text{sum } t \text{ naught}$. So, Further let $f'(t)$ be piecewise continuous on the interval 0 to ∞ , then the Laplace transform of $f'(t)$ exists and we have L of $f'(t)$ equal to s times L of $f(t)$ minus $f(0)$ for all s greater than γ .

(Refer Slide Time: 02:39)

Let us proof this theorem, we first will prove this theorem for the case when $f'(t)$ is a continuous Function on the interval 0 to ∞ . Let us say we call that every piecewise continuous Function need not be continuous, while a continuous function is always piecewise continuous. So let us assume, let us first discuss the proof of the theorem for the case when $f'(t)$ is continuous on 0 to ∞ .

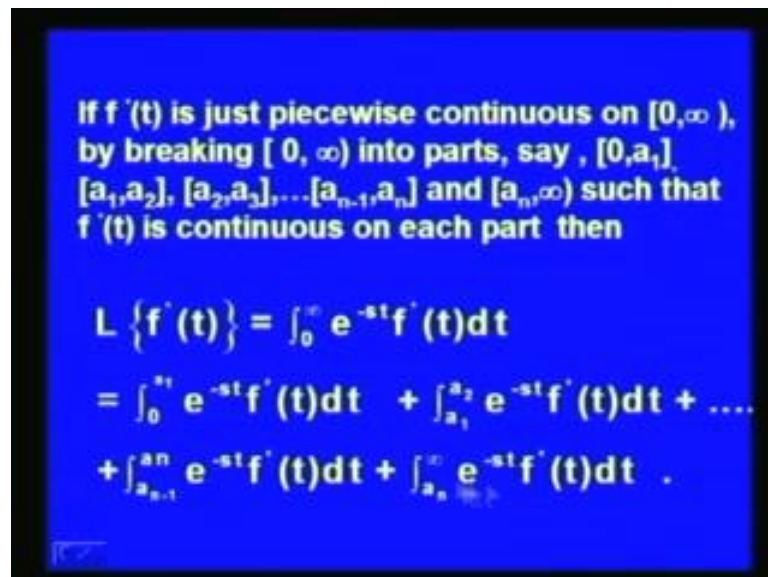

Then, the Laplace transform of $f'(t)$ which is equal to by definition of Laplace transform $\int_0^{\infty} e^{-st} f'(t) dt$ is equal to when we integrate by parts it will be equal to $e^{-st} f(t)$ evaluated at 0 to ∞ plus s times $\int_0^{\infty} e^{-st} f(t) dt$.

Now, since we have assumed that $f(t)$ is of exponential order γ , so mod of $f(t)$ is less than or equal to m times e to the power γt for large values of t . And therefore, $s > \gamma$

goes to infinity e^{-st} into $f(t)$ will go to 0 as t goes to infinity, because $f(t)$ is less than or equal to $M e^{-\gamma t}$.

So, $M e^{-st} f(t)$ will be less than or equal to $M e^{-s t}$ for $t > 0$. So, when $s > \gamma$ and $t \rightarrow \infty$, this quantity will go to 0 and at the lower limit its value is $f(0)$. So, we get $\int_0^\infty e^{-st} f'(t) dt = -f(0) + s \int_0^\infty e^{-st} f(t) dt$, so this proves the theorem for the case, when $f'(t)$ is continuous on the interval $0 < t < \infty$.

(Refer Slide Time: 04:33)

Now, if $f'(t)$ is just piecewise continuous on the interval $0 < t < \infty$, then what we do is, we break the interval $0 < t < \infty$ into finitely many parts say $0 < t < a_1$, $a_1 < t < a_2$, $a_2 < t < a_3$, ..., $a_{n-1} < t < a_n$ and $a_n < t < \infty$ such that $f'(t)$ is continuous on each part. Then by definition $L\{f'(t)\} = \int_0^\infty e^{-st} f'(t) dt$ it can be broken up into these $n+1$ integrals $\int_0^{a_1} e^{-st} f'(t) dt + \int_{a_1}^{a_2} e^{-st} f'(t) dt + \dots + \int_{a_{n-1}}^{a_n} e^{-st} f'(t) dt + \int_{a_n}^\infty e^{-st} f'(t) dt$.

(Refer Slide Time: 05:21)

Now, integrating by parts we have

$$L \{ f'(t) \}$$

$$= [e^{-st} f(t)]_0^{a_1} + s \int_0^{a_1} e^{-st} f(t) dt +$$

$$+ [e^{-st} f(t)]_{a_1}^{a_2} + s \int_{a_1}^{a_2} e^{-st} f(t) dt + \dots$$

$$+ [e^{-st} f(t)]_{a_{n-1}}^{a_n} + s \int_{a_{n-1}}^{a_n} e^{-st} f(t) dt +$$

$$+ [e^{-st} f(t)]_{a_n}^{\infty} + s \int_{a_n}^{\infty} e^{-st} f(t) dt$$

Now, let us integrate each integral let us evaluate each integral by integrating by parts, then the first integral on the right gives $e^{-st} f(t)$ from 0 to a_1 plus s times integral 0 to a_1 $e^{-st} f(t) dt$ plus second integral on the right gives $e^{-st} f(t)$ from a_1 to a_2 plus s times a_1 to a_2 $e^{-st} f(t) dt$ and so on.

The n th integral gives $e^{-st} f(t)$ from a_{n-1} to a_n plus s times integral over a_{n-1} to a_n $e^{-st} f(t) dt$ and the last integral gives on integration by parts $e^{-st} f(t)$ from a_n to infinity, and then plus s times integral over a_n to infinity $e^{-st} f(t) dt$.

(Refer Slide Time: 06:10)

$$\begin{aligned}
 & \mathcal{L}\{f'(t)\} \\
 &= \left[e^{-st} f(a_1) - f(0) \right] + s \int_0^{a_1} e^{-st} f(t) dt + \\
 &+ \left[e^{-sa_2} f(a_2) - e^{-sa_1} f(a_1) \right] + s \int_{a_1}^{a_2} e^{-st} f(t) dt + \dots \\
 &+ \left[e^{-sa_n} f(a_n) - e^{-sa_{n-1}} f(a_{n-1}) \right] + s \int_{a_{n-1}}^{a_n} e^{-st} f(t) dt + \\
 &+ \left[0 - e^{-sa_n} f(a_n) \right] + s \int_{a_n}^{\infty} e^{-st} f(t) dt. \\
 \\
 &= -f(0) + s \int_0^{\infty} e^{-st} f(t) dt \\
 &= -f(0) + s \mathcal{L}(f(t)), \quad s > \gamma.
 \end{aligned}$$

And hence, $\mathcal{L}\{f'(t)\}$ equal to $e^{-st} f(a_1) - f(0) + s \int_0^{a_1} e^{-st} f(t) dt + e^{-sa_2} f(a_2) - e^{-sa_1} f(a_1) + s \int_{a_1}^{a_2} e^{-st} f(t) dt + \dots + e^{-sa_n} f(a_n) - e^{-sa_{n-1}} f(a_{n-1}) + s \int_{a_{n-1}}^{a_n} e^{-st} f(t) dt + 0 - e^{-sa_n} f(a_n) + s \int_{a_n}^{\infty} e^{-st} f(t) dt$.

And then we get the last integral is equal to $0 - e^{-sa_n} f(a_n) + s \int_{a_n}^{\infty} e^{-st} f(t) dt$. This 0 comes when we take the limit of $e^{-st} f(t)$ as $t \rightarrow \infty$, because $f(t)$ is of exponential order. And then these terms will all cancel out $e^{-sa_1} f(a_1)$ will cancel with these $e^{-sa_2} f(a_2)$ will cancel with the next term coming in the next term, and then $e^{-sa_n} f(a_n)$ will also cancel with this. So, ultimately on simplification the right hand side becomes $-f(0) + s \int_0^{\infty} e^{-st} f(t) dt$. Because, $\int_0^{a_1} e^{-st} f(t) dt + \int_{a_1}^{a_2} e^{-st} f(t) dt + \dots + \int_{a_{n-1}}^{a_n} e^{-st} f(t) dt + \int_{a_n}^{\infty} e^{-st} f(t) dt$ can be combined together and we get the integral $\int_0^{\infty} e^{-st} f(t) dt$.

So, we get this Further equal to $-f(0) + s \mathcal{L}(f(t))$ and thus in the case when $f'(t)$ is just piecewise continuous, again we get the Laplace

transform of $f'(t)$ is s times Laplace transform of the function t minus $f(0)$ whenever s is greater than γ .

(Refer Slide Time: 08:15)

Remark (Extension of Theorem 1).

If $f(t)$ is continuous, except for an ordinary discontinuity (finite jump) at $t = a (> 0)$ and the other conditions remain the same then

$$L\{f'\} = sL\{f\} - f(0) - (f(a + 0) - f(a - 0))e^{-as}.$$

Proof. We may write

$$L\{f'(t)\} = \int_0^{\infty} e^{-st} f'(t) dt$$

$$= \int_0^a e^{-st} f'(t) dt + \int_a^{\infty} e^{-st} f'(t) dt$$

Now, let us study an extension of theorem 1, suppose that the Function $f(t)$ is not continuous, then it has the discontinuity at the point t equal to a , and the discontinuity is the ordinary discontinuity. So, let us assume that the function $f(t)$ is continuous for all t greater than or equal to 0 except for an ordinary discontinuity, ordinary discontinuity means when t times 2 a minus 0 that is t times 2 a from the left side or t times 2 a from the right side, we the function $f(t)$ tends to a finite limit. So, it has got finite jumps on either side of t equal to a and all the other conditions of the theorem 1 remain the same.

Then, the Laplace transform of $f'(t)$ is equal to s times Laplace transform of $f(t)$ minus $f(0)$ minus $f(a + 0) - f(a - 0)$ which is the right hand limit of $f(t)$ as t times 2 a minus $f(a - 0)$ which is the left hand limit of $f(t)$ as t times 2 a into e to the power minus a s .

Let us prove this result, by definition we may write Laplace transform of $f'(t)$ as integral 0 to infinity e^{-st} into $f'(t) dt$. Now, let us break this integral on the right side into two parts integral over 0 to a e^{-st} into $f'(t) dt$ and the other integral over a to infinity e^{-st} into $f'(t) dt$, and then we integrate by parts.

(Refer Slide Time: 09:54)

$$\begin{aligned}
 &= \left[e^{-st} f(t) \right]_0^a + s \int_0^a e^{-st} f(t) dt \\
 &+ \left[e^{-st} f(t) \right]_a^{\infty} + s \int_a^{\infty} e^{-st} f(t) dt \\
 &= \left[e^{-sa} f(a-0) - f(0) \right] + s \int_0^a e^{-st} f(t) dt \\
 &+ \left[0 - e^{-sa} f(a+0) \right] + s \int_a^{\infty} e^{-st} f(t) dt \\
 &= -f(0) + e^{-sa} [f(a-0) - f(a+0)] + s \int_0^{\infty} e^{-st} f(t) dt \\
 \Rightarrow L(f') &= sL(f) - f(0) - (f(a+0) - f(a-0))e^{-sa} .
 \end{aligned}$$

So, then the first integral on the right gives $e^{-st} f(t)$ evaluated at 0 and a plus s times integral over 0 to a $e^{-st} f(t) dt$. The second integral on integration by part gives $e^{-st} f(t)$ evaluated at 0 to infinity plus s times integral over a to infinity $e^{-st} f(t) dt$.

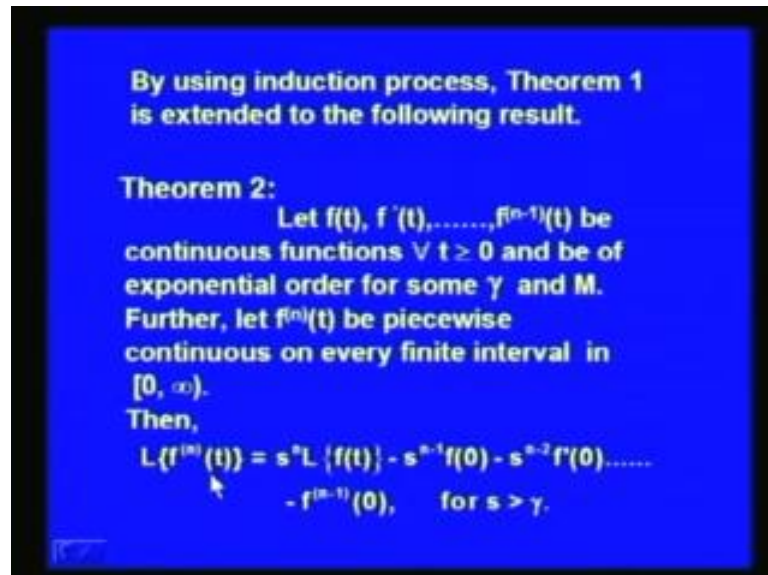

So, when t tends to a here, then t will tend to a from the left side, so $e^{-st} f(t)$ will tend to $e^{-sa} f(a-0)$ where $f(a-0)$ is the limit of $f(t)$ as t tends to a from the left. And then minus $f(0)$ we get after we put the lower limit here, t equal to 0 and then plus s times integral 0 to a $e^{-st} f(t) dt$ and here, when t tends to infinity $e^{-st} f(t)$ goes to 0, because $f(t)$ is of exponential order.

And, when we try to put the lower limit t will tend to a , and it will tend to a from the right, because the interval is from a to infinity. So, when t tends to a from the right $e^{-st} f(t)$ will tend to $e^{-sa} f(a+0)$ where $f(a+0)$ is the right hand limit of $f(t)$ as t tends to a from the right plus 0 is the right hand limit of $f(t)$ as t tends to a from the right plus s times integral over a to infinity $e^{-st} f(t) dt$.

And, when we combine these two integrals, we get integral over 0 to infinity $e^{-st} f(t) dt$. So, on simplification this right hand side of the equation gives minus $f(0)$ plus $e^{-sa} [f(a-0) - f(a+0)]$ plus s times integral 0 to infinity $e^{-st} f(t) dt$, which is same as $L(f')$

equal to s into $L f$ minus $f(0)$ minus $f'(0)$ plus $f''(0)$ minus $f'''(0)$ plus $f^{(4)}(0)$ minus $f^{(5)}(0)$ into e^{-st} to the power n which gives the required result.

(Refer Slide Time: 12:08)

Now, let us use the induction process on theorem 1, so on using induction we have the following result. Let $f(t), f'(t)$ and so on $f^{(n-1)}(t)$ be continuous functions for all t greater than or equal to 0 and be of exponential order for some γ and M . Further, let the n th derivative of $f(t)$ be piecewise continuous on every finite interval in the range t greater than or equal to 0 that is the interval 0 to infinity.

Then, the Laplace transform of n the derivative of $f(t)$ that is $f^{(n)}(t)$ is equal to s^n into $L f(t)$ minus s^{n-1} into $f(0)$ minus s^{n-2} into $f'(0)$ and so on minus $f^{(n-1)}(0)$ for all s greater than γ . Now, this theorem is easy to prove by induction on n for n equal to 1 it holds by theorem 1 and assuming it for $n-1$, we can easily show it for n by induction.

(Refer Slide Time: 13:14)

Example. Find the Laplace transform of the Bessel Function J_1 .

Solution : We know that $J_0'(x) = -J_1(x)$.

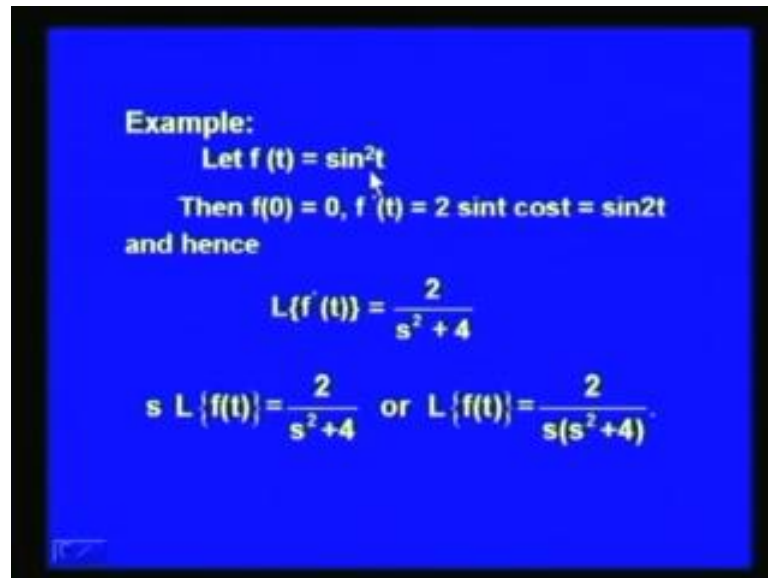

Hence, $L(J_1(x)) = -L(J_0'(x))$

$$= -[s L(J_0(x)) - J_0(0)]$$
$$= -\left[s \frac{1}{\sqrt{s^2+1}} - 1 \right] = 1 - \frac{s}{\sqrt{s^2+1}}$$

Now, let us take an example based on the Laplace transform of the derivative of a Function, let us find the Laplace transform of the Bessel function of order one that is J_1 . We know that by the properties of Bessel functions of first time, we know that Laplace transform, we know that the derivative of $J_0(x)$ is equal to minus $J_1(x)$. So, if we want to find the Laplace transform of $J_1(x)$ we can write by using the linearity of the operator L Laplace transform of $J_1(x)$ equal to minus 1 of $J_0'(x)$ and which will be equal to minus 1 of $J_0'(x)$ minus $J_0(x)$ evaluated at 0 using the theorem 1.

So, this is equal to minus s times upon Laplace transform of $J_0(x)$ is equal to 1 over square root $s^2 + 1$ which we had shown in our previous lecture on the Laplace transformation. So, s times 1 over the square root $s^2 + 1$ minus $J_0(x)$ if you put x equal to 0 in the series expansion of $J_0(x)$, then you get the value $J_0(0) = 1$. So, we get the Laplace transform of $J_1(x) = 1 - \frac{s}{\sqrt{s^2 + 1}}$.

(Refer Slide Time: 14:39)

Example:
Let $f(t) = \sin^2 t$
Then $f(0) = 0$, $f'(t) = 2 \sin t \cos t = \sin 2t$
and hence
$$L\{f'(t)\} = \frac{2}{s^2 + 4}$$

$$s L\{f(t)\} = \frac{2}{s^2 + 4} \quad \text{or} \quad L\{f(t)\} = \frac{2}{s(s^2 + 4)}$$

Let us now take another example, let us say $f(t)$ equal to $\sin^2 t$ we want to find the Laplace transform of $f(t)$. And we cannot find this Laplace transform of $f(t)$ by directly from the known results on the Laplace transform of elementary function which we have studied in the previous lecture of Laplace transformation. But, we can do it either by writing $\sin^2 t$ as $\frac{1 - \cos 2t}{2}$ and using the linearity property of L and the Laplace transform of $\cos 2t$, we can also find the Laplace transform of $f(t)$ equal to $\sin^2 t$ using theorem 1, as we are going to see now.

So, $f(0)$ equal to 0 $f'(t)$ is equal to $2 \sin t \cos t$ that is it is equal to $\sin 2t$, and we can see that $f(t)$ is the continuous function for all t greater than or equal to 0 $f'(t)$ of exponential order. Because $f(t)$ is the bounded function and then its derivative $f'(t)$ is $\sin 2t$ which is also a continuous function for all t greater than or equal to 0. So, we can apply theorem 1 and by theorem 1, then Laplace transform of $f'(t)$.

Now, Laplace transform of $f'(t)$ we can rightly write using the known results we know that Laplace transform of $\sin at$ is $\frac{a}{s^2 + a^2}$. So, Laplace transform of $f'(t)$ will be equal to $\frac{2}{s^2 + 4}$. Now, Laplace transform of $f'(t)$ is equal to s into Laplace transform of $f(t)$ minus $f(0)$, but $f(0)$ is 0.

So, $L\{f'(t)\} = s L\{f(t)\} - f(0)$ becomes $s L\{f(t)\} = \frac{2}{s^2 + 4}$ which is equal to $\frac{2}{s^2 + 4}$ dividing by s , we get Laplace transform of the function $f(t)$ that is Laplace transform of $\sin^2 t$

s^2 over s into s^2 plus 4. So, by using theorem 1 we can find the Laplace transform of $f(t)$ equal to $\sin^2 t$.

(Refer Slide Time: 16:44)

Example:
Solve the initial value problem
 $y'' - 3y' + 2y = 4t + e^{3t}$, $y(0) = 1$ and $y'(0) = -1$
 Taking Laplace transform of the differential equation, we obtain
 $[s^2Y(s) - sy(0) - y'(0)] - 3[sY(s) - y(0)] + 2Y(s)$
 $= \frac{4}{s^2} + \frac{1}{s-3}$
 where $L\{y(t)\} = Y(s)$.

Let us, now study how we can find the solution of a differential equation with the given initial conditions the conditions are $y(0)$ equal to 1 and $y'(0)$ equal to minus 1. The differential equation is $y'' - 3y' + 2y = 4t + e^{3t}$. Now, we will take the Laplace transform of the given differential equation on both sides when we take the Laplace transform of y'' what we get is $s^2Y(s) - sy(0) - y'(0)$ using the theorem 2. And then minus 3 times Laplace transform of y' will become $sY(s) - y(0)$ plus 2 times Laplace transform of y will become $Y(s)$.

And this is equal to 4 times Laplace transform of t that is $\frac{1}{s^2}$ plus Laplace transform e^{3t} that is $\frac{1}{s-3}$. So, we are making use of theorem 2 here, and the linearity property of the Laplace operator, where we are assuming that $L\{y(t)\}$ that is Laplace transform of $y(t)$ is equal to $Y(s)$.

(Refer Slide Time: 18:01)

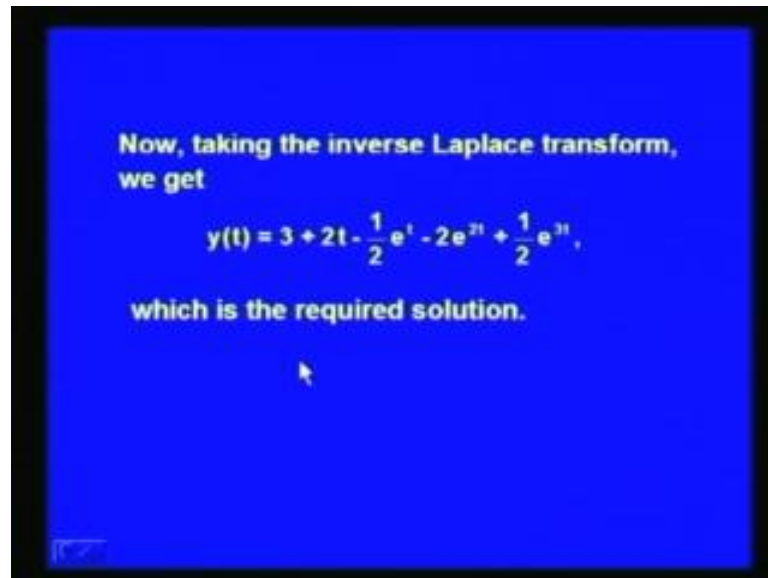

Using the given initial conditions, after simplification we get

$$Y(s) = \frac{s^4 - 7s^3 + 13s^2 + 4s - 12}{s^2(s-1)(s-2)(s-3)}$$
$$= \frac{3}{s} + \frac{2}{s^2} + \frac{1}{2(s-1)} - \frac{2}{s-2} + \frac{1}{2(s-3)}$$

after breaking into partial fractions.

Now, let us use the given initial conditions that is $y(0)$ equal to 1 and the initial condition for $y'(0)$ will get that $Y(s)$ after simplification, the value of $Y(s)$ comes out to be equal to $s^4 - 7s^3 + 13s^2 + 4s - 12$ over $s^2(s-1)(s-2)(s-3)$ which is the rational function of s and is a proper fraction. So, we can break it into its partial fractions and after breaking it into partial fractions we get that $Y(s)$ becomes equal to $\frac{3}{s} + \frac{2}{s^2} + \frac{1}{2(s-1)} - \frac{2}{s-2} + \frac{1}{2(s-3)}$.

(Refer Slide Time: 18:55)

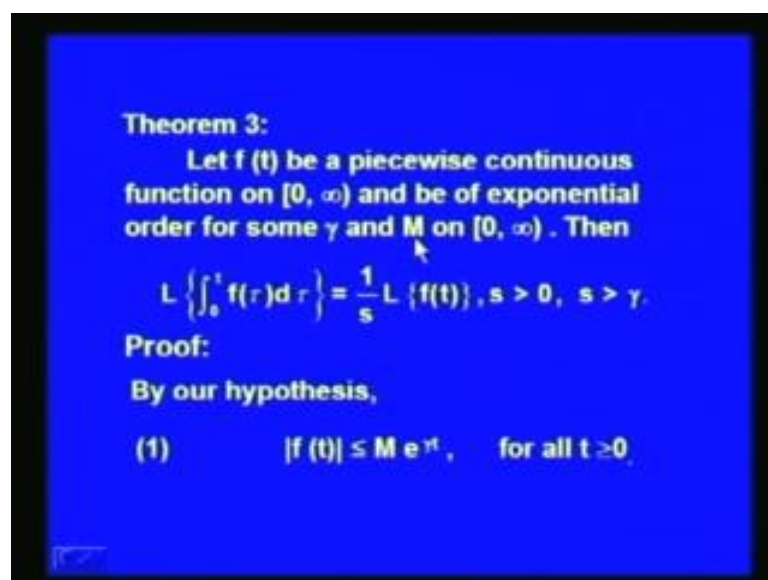

Now, taking the inverse Laplace transform, we get

$$y(t) = 3 + 2t - \frac{1}{2} e^t - 2e^{2t} + \frac{1}{2} e^{3t},$$

which is the required solution.

Now in order to find the desired function by t we will take the inverse Laplace transform on both sides of the last equation. So, we get Laplace inverse Laplace transform of y equal to y , y is equal to then 3 plus 2 t minus half e to the power t minus 2 times e to the power 2 t plus 1 by 2 e to the power 3 t which is the required solution of the given initial value problem.

(Refer Slide Time: 19:26)

Theorem 3:
Let $f(t)$ be a piecewise continuous function on $[0, \infty)$ and be of exponential order for some γ and M on $[0, \infty)$. Then

$$L \left\{ \int_0^t f(\tau) d\tau \right\} = \frac{1}{s} L \{ f(t) \}, s > 0, s > \gamma.$$

Proof:
By our hypothesis,

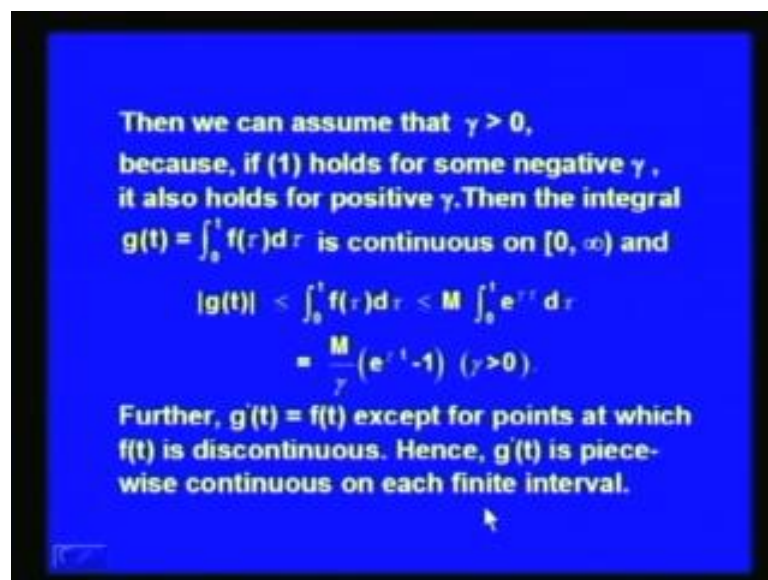

(1) $|f(t)| \leq M e^{\gamma t}$, for all $t \geq 0$.

Now, let us study next the theorem which is based on the Laplace transform of integral of a Function and we see that it again transforms into an algebraic operation Laplace

transform of $f(t)$ is divided by s . So, let $f(t)$ be a piecewise continuous function on the interval $[0, \infty)$ and be of exponential order for some γ and M on the interval $[0, \infty)$. Then the Laplace transform of $\int_0^t f(\tau) d\tau$ is equal to $\frac{1}{s}$ by the Laplace transform of $f(t)$, whenever s is greater than 0 and s is greater than γ .

So, by our hypothesis that $f(t)$ is of exponential order for some γ and M on $[0, \infty)$ and that $f(t)$ is piecewise continuous function on the interval $[0, \infty)$, it follows that $|f(t)|$ is less than or equal to some constant m into $e^{\gamma t}$ for all t greater than or equal to 0 . This M may not be the same as the m here in the theorem.

(Refer Slide Time: 20:41)

Now, we can assume here that γ is greater than 0 , because if the equation 1 that $|f(t)|$ is less than or equal to M times $e^{\gamma t}$ holds for some negative γ then clearly it also holds for a positive γ . And hence, γ can be assumed to be positive.

Now, then the integral $\int_0^t g(t) dt$ equal to $\int_0^t \int_0^t f(\tau) d\tau dt$ it is a continuous function on the interval $[0, \infty)$ and $|g(t)|$ is less than or equal to $\int_0^t f(\tau) d\tau$ less than or equal to M times $\int_0^t e^{\gamma \tau} d\tau$ and when we integrate $e^{\gamma \tau}$ and put the limits we get the right hand we get this value of the integral as $\frac{e^{\gamma t} - 1}{\gamma}$, where γ is positive.

Further, we found we find that $g(t)$ is equal to $\int_0^t f(\tau) d\tau$ is $g'(t)$ equal to $f(t)$ except for those points where the Function $f(t)$ is discontinuous. Hence, $g'(t)$ is a piecewise continuous Function on each finite interval.

(Refer Slide Time: 22:02)

Thus, we have

$$L(f(t)) = L(g'(t)) = sL(g(t)) - g(0) \quad (s > \gamma)$$

Since $g(0) = 0$, it follows that

$$L(g(t)) = \frac{L(f(t))}{s}$$

or $L\left(\int_0^t f(\tau) d\tau\right) = \frac{L(f(t))}{s}$,

which completes the proof.

Consequently,

$$L^{-1}\left(\frac{F(s)}{s}\right) = \int_0^t f(\tau) d\tau.$$

where $L(f(t)) = F(s)$.

And thus, we get $L(f(t))$ equal to $L(g'(t))$ and $L(g'(t))$ is equal to s times $L(g(t))$ minus $g(0)$ by the theorem 1. So, this will give us since $g(0)$ equal to 0 , it follows that $L(g(t))$ is equal to $L(f(t))$ over s or we may say $L\left(\int_0^t f(\tau) d\tau\right)$ is equal to $L(f(t))$ over s which completes the proof of the theorem. Consequently $L^{-1}\left(\frac{F(s)}{s}\right)$ is equal to $\int_0^t f(\tau) d\tau$, that is the inverse Laplace transform of $\frac{F(s)}{s}$ gives $\int_0^t f(\tau) d\tau$.

(Refer Slide Time: 23:01)

Example:
Find $L^{-1}\left\{\frac{1}{s^2(s^2+a^2)}\right\}$
Since $L^{-1}\left\{\frac{1}{(s^2+a^2)}\right\} = \frac{\sin at}{a}$
by Theorem 3 we have
 $L^{-1}\left\{\frac{1}{s(s^2+a^2)}\right\} = \int_0^t \frac{\sin ar}{a} d\tau$

Now, let us apply this theorem to find the inverse Laplace transform of L over s square into s square plus a square. We know that the inverse Laplace transform of L over s square plus a square is $\sin at$ over a . So, by the previous theorem that is theorem 3 we have inverse Laplace transform of Fs over s Fs we take as 1 over s square plus a square. So, L^{-1} of $f s$ over s that is 1 over s into s square plus a square will be equal to integral of $\sin a \tau$ over $a d \tau$ when integral over 0 to t $\sin a \tau$ over $a d \tau$.

(Refer Slide Time: 23:44)

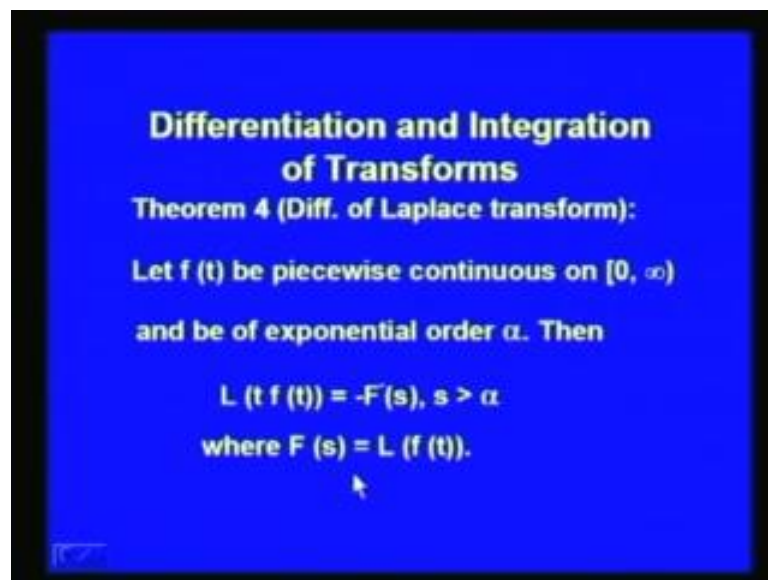

$$= \frac{1}{a^2} (-\cos ar)'_0^t = \frac{1}{a^2} (1 - \cos at)$$

Again, applying Theorem 3 we obtain

$$L^{-1}\left\{\frac{1}{s^2(s^2+a^2)}\right\} = \frac{1}{a^2} \int_0^t (1 - \cos ar) d\tau$$
$$= \frac{1}{a^2} \left(\tau - \frac{\sin ar}{a} \right)_0^t = \frac{1}{a^2} \left(t - \frac{\sin at}{a} \right)$$

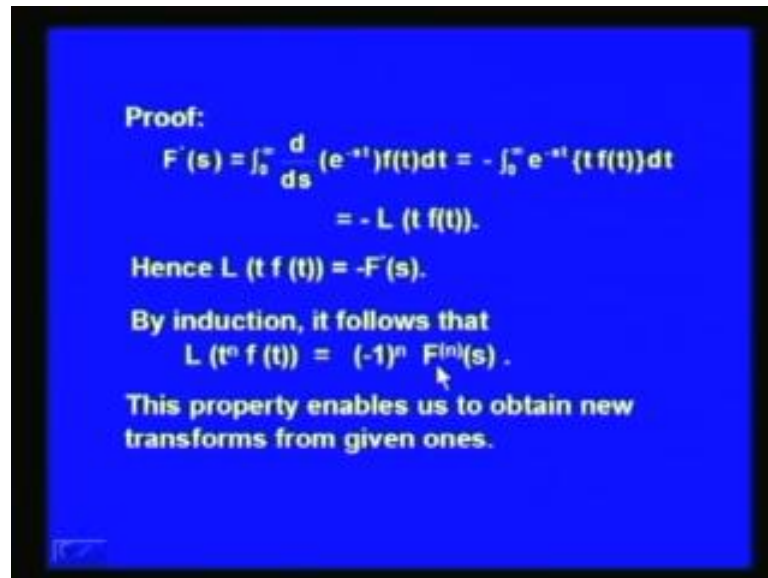

And, when we evaluate the integral and substitute the limit the right hand side becomes $1/a^2$ by a square into $-\cos at$ evaluated at 0 and t , so this is equal to $1/a^2$ $1 - \cos at$. Now, we again apply theorem 3 to the Function $F(s) = 1/(s^2 + a^2)$ into $s^2 + a^2$. So, then L^{-1} of $F(s)$ over s that is $1/(s^2 + a^2)$ into $s^2 + a^2$ will be equal to $1/a^2$ integral 0 to t $1 - \cos a\tau$ $d\tau$ and when we integrate $1 - \cos a\tau$ with respect to τ what we get is $\tau - \sin a\tau/a$ and the when we evaluate it at 0 and t and substitute and multiply by $1/a^2$ we get $1/a^2$ into $t - \sin at/a$. So, this theorem helps us in finding the inverse Laplace transform of many new Functions once the Laplace transform of some other Functions are known.

(Refer Slide Time: 24:55)

Now, let us study differentiation and integration of transforms, so first theorem on differentiation of Laplace transform is the following. Let $f(t)$ be piecewise continuous on the interval 0 to infinity and be of exponential order α . Then $L(t f(t))$ is equal to $-F'(s)$ whenever s is greater than α , so this theorem tells us that whenever we differentiate the Laplace transform of a certain Function $f(t)$ with respect to s . Then the function $f(t)$ gets multiplied by t that is Laplace transform $t f(t)$ becomes $-F'(s)$ whenever we differentiate the Laplace transform by function $f(t)$, the original function $f(t)$ gets multiplied by $-t$. So, we get $L(t f(t))$ equal to $-F'(s)$ whenever s is greater than α , $F(s)$ here has been we know already is $L(f(t))$.

(Refer Slide Time: 25:47)

Let us prove this theorem, we can write $F'(s)$ equal to $\frac{d}{ds}$ of $F(s)$ that is $\frac{d}{ds}$ of $\int_0^{\infty} e^{-st} f(t) dt$. So, $\frac{d}{ds}$ can be brought inside the integral $\int_0^{\infty} \frac{d}{ds} (e^{-st}) f(t) dt$ because s and t are independent of each other and this will be equal to when we differentiate with respect to s . So, this will be equal to e^{-st} into $-t$. So, $-t$ this minus comes outside the integral and t will combine with the function $f(t)$, and then this is nothing but minus Laplace transform of $t f(t)$, so $-L(t f(t))$. Hence, $L(t f(t))$ is equal to $-F'(s)$.

Now, again we can use induction on n and can show that Laplace transform of $t^n f(t)$ is equal to $(-1)^n F^{(n)}(s)$. When you take n equal to 1 here, then the result follows from this theorem $f(t)$ equal to $-F'(s)$, so assuming that the result holds for n we can easily show it for $n+1$.

Now, this property of the Laplace transform enables us to obtain new transforms from the given ones, that is if we know certain Laplace transform $F(s)$ by differentiating it. We can get new transforms that is we can get the transforms $F'(s)$ $F''(s)$ we just have to multiply $f(t)$ by $(-1)^n t^n$.

(Refer Slide Time: 27:33)

Example. Evaluate the integral $\int_0^{\infty} t e^{-3t} \sin t dt$.

Solution. We know that

$$\int_0^{\infty} t e^{-st} \sin t dt = L(t \sin t)$$
$$= -\frac{d}{ds} \left(\frac{1}{s^2 + 1} \right) = \frac{2s}{(s^2 + 1)^2}$$

Putting $s = 3$ in this integral, we get

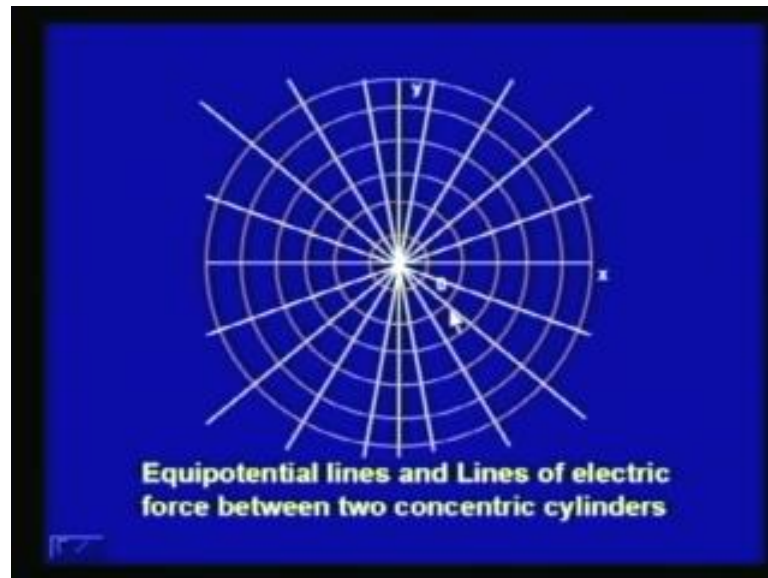

$$\int_0^{\infty} t e^{-3t} \sin t dt = \frac{2 \times 3}{(3^2 + 1)^2} = \frac{3}{50}$$

So, let us take an example on this theorem, let us evaluate the integral of integral 0 to infinity $t e^{-3t} \sin t dt$. If we identify this integral with the definition of the Laplace transform then we note that integral 0 to infinity $t e^{-st} \sin t dt$, this is nothing but the Laplace transform of $t \sin t$, because e^{-st} into $t \sin t$ it is and then it the integral 0 to infinity.

So, this is Laplace transform of $t \sin t$ and Laplace transform of $t \sin t$ by the previous theorem and differentiation of Laplace transform is minus d/ds of Laplace transform of $f(t) = \sin t$. And Laplace transform $\sin t$ we know it is $1/(s^2 + 1)$, when we differentiated with respect to s and multiplied by minus 1 we get $2s/(s^2 + 1)^2$.

So, now, let us put we want the value of this integral. So, let us put s equal to 3 here in order to get the value of the desired integral. So, putting s equal to 3 here, what we get is integral 0 to infinity $t e^{-3t} \sin t dt = 2 \times 3 / (3^2 + 1)^2 = 3/50$.

(Refer Slide Time: 28:53)

So, they are orthogonal trajectories of each other.

(Refer Slide Time: 28:59)

Example. Evaluate $L(t \sin^2 3t)$.

Solution. We have

$$L(\sin^2 3t) = L\left(\frac{1 - \cos 6t}{2}\right)$$
$$= \frac{1}{2} \left(\frac{1}{s} - \frac{s}{s^2 + 36} \right) = \frac{18}{s(s^2 + 36)}$$

Therefore, $L(t \sin^2 3t) = (-1) \frac{d}{ds} \left(\frac{18}{s(s^2 + 36)} \right)$

$$= -18(-1)(s^2 + 36s)^{-2} (3s^2 + 36)$$
$$= \left(\frac{54(s^2 + 12)}{s^2 (s^2 + 36)^2} \right) *$$

Likewise we will study example based on the last theorem let us say evaluate the Laplace transform of $t \sin^2 3t$. Let us first note that the Laplace transform of $\sin^2 3t$ is same as Laplace transform of $\frac{1 - \cos 6t}{2}$ and using the linearity property of the Laplace operator L we can write it as half of Laplace transform of $1 - \cos 6t$ which is $\frac{1}{s} - \frac{s}{s^2 + 36}$. So, when we simplify this we get the right hand side equal to $\frac{18}{s(s^2 + 36)}$.

And now, if we apply the theorem on derivative differentiation of Laplace transform then we get Laplace transform of $t^3 e^{-3t}$ equal to minus of d over $d s$ of 18 over s times s square plus 36 , which is equal to minus 18 into minus 1 s cube plus 36 raise to the power minus 2 into $3 s$ square plus 36 . Simplification this becomes 54 into s square plus 12 over s square into s square plus 36 whole square.

(Refer Slide Time: 30:22)

Example. Evaluate $L(t^3 e^{-3t})$.

Solution. Since, $L(e^{-3t}) = \frac{1}{s+3}$,

we get

$$L(t^3 e^{-3t}) = (-1)^3 \frac{d^3}{ds^3} \left(\frac{1}{s+3} \right)$$

$$= \frac{3!}{(s+3)^4}$$

$$= \frac{6}{(s+3)^4}$$

Now, let us evaluate the Laplace transform of t^3 into e to the power minus $3 t$. We know that Laplace transform of e to the power minus $3 t$ is 1 over s plus 3 and therefore, by using the last theorem we get the Laplace transform of t^3 into e to the power minus $3 t$ as minus 1 to the power 3 into d cube over $d s$ cube 1 over s plus 3 which is equal to 3 factorial over s plus 3 raise to the power 4 and which is equal to 6 over s plus 3 raise to the power 4 .

(Refer Slide Time: 31:04)

Example. Solve $ty'' + (1 - 2t)y' - 2y = 0$
with $y(0) = 1, y'(0) = 2.$

Solution. Let $L(y(t)) = \bar{y}(s)$. Taking Laplace transform of given equation, we get

$$L(ty'') + L((1 - 2t)y') - 2L(y) = 0$$

or $(-1) \frac{d}{ds} [s^2 \bar{y}(s) - s y(0) - y'(0)] +$
 $+ [s \bar{y}(s) - y(0)] +$
 $+ 2 \frac{d}{ds} [s \bar{y}(s) - y(0)] - 2 \bar{y}(s) = 0.$

Now, let us solve a differential equation of second order, let us consider the differential equation $t y'' + (1 - 2t)y' - 2y = 0$ with the given initial condition as $y(0) = 1$ and $y'(0) = 2$. Let us denote the Laplace transform of $y(t)$ as $\bar{y}(s)$ and then when we take the Laplace transform of the given differential equation we will get a Laplace transform $t y'' + (1 - 2t)y' - 2y = 0$ to Laplace transform of 0 which is equal to 0. This follows using the linearity of the operator L .

Or now Laplace transform of $t y''$ is equal to $-1 \frac{d}{ds}$ of Laplace transform of y'' by the previous theorem. So, we get Laplace transform y'' as $s^2 \bar{y}(s) - s y(0) - y'(0)$ plus Laplace transform of y' , we are using the linearity here linearity property the operator L , so first if I write the Laplace transform y' here which is $s \bar{y}(s) - y(0)$.

Then, we have -2 times Laplace transform of $t y'$ and Laplace transform of $t y'$ is $-1 \frac{d}{ds}$ of Laplace transform of y' which is $s \bar{y}(s) - y(0)$. So, Laplace transform of $-2 t y'$ becomes $+2 \frac{d}{ds}$ of $s \bar{y}(s) - y(0)$ minus 2 times Laplace transform of y is $\bar{y}(s)$. So, we get $-2 \bar{y}(s) = 0$.

(Refer Slide Time: 32:51)

$$\frac{dy}{ds}(s^2 - 2s) = -sy$$

or $\frac{dy}{y} = -\frac{ds}{(s-2)}$,

which on integration gives

$$\ln y = -\ln(s-2) + \ln A.$$

or $y = \frac{A}{s-2}$.

Taking inverse Laplace transform of both sides, we get

$$y = Ae^{2t} \Rightarrow y = e^{2t} \text{ as } y(0) = 1.$$

And, on simplification what we get is $\frac{dy}{ds}(s^2 - 2s) = -sy$ using the initial conditions. So, we can now separate the variables y and s and we get $\frac{dy}{y} = -\frac{ds}{s-2}$. Now, on integration what we get is $\ln y = -\ln(s-2) + \ln A$ which gives us $y = \frac{A}{s-2}$. And now, if we take the inverse Laplace transform of this equation we will get inverse Laplace transform of y by t and the right side will be using linearity property A times inverse Laplace transform of $\frac{1}{s-2}$ which will be e^{2t} .

So, y becomes equal to Ae^{2t} , now let us make use of the initial condition that is $y(0) = 1$. The value of A turns out to be equal to 1 and we get the solution of the given differential equation as $y = e^{2t}$.

(Refer Slide Time: 34:03)

Example. Find $L^{-1}\left(\frac{s}{(s+1)^2(s^2+1)}\right)$

Solution. Here $F(s) = \frac{A}{(s+1)} + \frac{B}{(s+1)^2} + \frac{Cs+D}{(s^2+1)}$

$\Rightarrow A=0, B=-1/2, C=0, D=1/2.$

Hence, $F(s) = \frac{1}{2(s^2+1)} - \frac{1}{2(s+1)^2}$

$\Rightarrow L^{-1}(F(s)) = \frac{1}{2}\sin t - \frac{1}{2}te^{-t}.$

Next, we find the inverse Laplace transform of s over s plus 1 whole square into s square plus 1. So, let us denote by $F(s)$ s over s plus 1 whole square into s square plus 1, when we break it into when we break $F(s)$ into its partial fractions $F(s)$ is taken as s over s plus 1 whole square into s square plus 1 here. So, when we break $F(s)$ into its partial fractions we write it as a over s plus 1 plus b over s plus 1 whole square plus c plus d over s square plus 1.

And, when we take the LCM here, and then use $F(s)$ equal to s over s plus 1 whole square into s square plus 1 and evaluate the values of the constants a b c d what we get is a is equal to 0 b equal to minus half c equal to 0 and d equal to half. And hence, the value of $F(s)$ is equal to after making $F(s)$ into its partial fractions we get $F(s)$ as 1 over 2 into s square plus 1 minus 1 over 2 into s plus 1 whole square.

So, now let us take inverse Laplace transform of $F(s)$ and L^{-1} of $F(s)$ is equal to then half of L^{-1} of 1 over s square plus 1 which is $\sin t$ minus half of L^{-1} of 1 over s plus 1 whole square. Now, we know that Laplace inverse Laplace transform of 1 over s plus 1 is e to the power minus t .

So, when we differentiate 1 over s plus 1 with respect to s that is d over ds of 1 over s plus 1 becomes -1 over s plus 1 whole square. And that is the inverse Laplace transform of that is equal to t into e to the power minus t inverse Laplace transform of 1 over s plus 1 whole square is t into e to the power minus t by the previous theorem. So,

we get the inverse Laplace transform of the desired Function of $s^{-1/2} \sin t$ minus half $t^{-1/2}$ into e^{-t} to the power minus t .

(Refer Slide Time: 36:18)

Example: Find the inverse Laplace transform of

$$\ln\left(1 + \frac{a^2}{s^2}\right).$$

Solution. We have

$$\frac{d}{ds} \ln\left(1 + \frac{a^2}{s^2}\right) = \frac{1}{1 + \frac{a^2}{s^2}} \left(\frac{-2a^2}{s^3}\right)$$

$$= \left(\frac{-2a^2}{s(s^2 + a^2)}\right) = -2\left(\frac{1}{s} - \frac{s}{s^2 + a^2}\right).$$

Now, let us find the inverse Laplace transform of the logarithmic function $\ln\left(1 + \frac{a^2}{s^2}\right)$. What we will do is, we will first take the derivative of $\ln\left(1 + \frac{a^2}{s^2}\right)$ with respect to s . So, we see that $\frac{d}{ds} \ln\left(1 + \frac{a^2}{s^2}\right)$ is $\frac{1}{1 + \frac{a^2}{s^2}} \times \left(\frac{-2a^2}{s^3}\right)$, which on simplification gives us $\frac{-2a^2}{s(s^2 + a^2)}$ when we break it into its partial fractions what we get is $-2\left(\frac{1}{s} - \frac{s}{s^2 + a^2}\right)$.

So, if we now take the inverse Laplace transform on both sides of this equation, we will get $L^{-1}\left(\frac{d}{ds} \ln\left(1 + \frac{a^2}{s^2}\right)\right) = -2\left(L^{-1}\left(\frac{1}{s}\right) - L^{-1}\left(\frac{s}{s^2 + a^2}\right)\right)$.

(Refer Slide Time: 37:21)

Hence,

$$L^{-1}\left[\frac{d}{ds}\ln\left(1+\frac{a^2}{s^2}\right)\right] = -2(1-\cos at)$$

$$= -tL^{-1}\left(\ln\left(1+\frac{a^2}{s^2}\right)\right)$$

which implies that

$$L^{-1}\left(\ln\left(1+\frac{a^2}{s^2}\right)\right) = \frac{2(1-\cos at)}{t}.$$

So, we get L inverse of d over d s of l n 1 plus a square by s square as minus 2 times 1 minus cos a t and L inverse d over d s of F s we know l inverse of d over d s of F s is minus t times f t. So, we get l inverse of d over d s of l n 1 plus a square by s square as minus t times L inverse of F s, this is minus t times of f t. So, minus t times L inverse of l n 1 plus a square by s square, so what we get is minus t times L inverse l n 1 plus a square by s square equal to minus 2 times 1 minus 1 minus cos a t. So, this implies that an inverse if l n 1 plus a square by s square is equal to 2 times 1 minus cos a t over t.

(Refer Slide Time: 38:11)

Theorem 5. (Integration of Laplace Transform). If $f(t)$ satisfies the conditions of the existence theorem and

$$\lim_{t \rightarrow 0^+} \frac{f(t)}{t} \text{ exists, then we have}$$

$$L\left(\frac{f(t)}{t}\right) = \int_s^{\infty} F(u)du, \quad (u > \gamma),$$

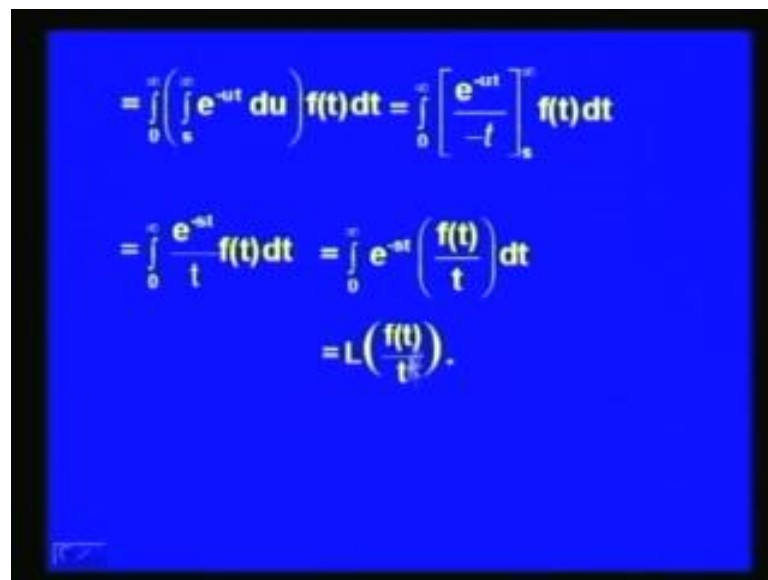

where $L(f(t)) = F(u)$.

Proof. By definition

$$\int_s^{\infty} F(u)du = \int_s^{\infty} \left(\int_0^{\infty} e^{-ut} f(t) dt \right) du$$

Now, let us study what happens when we integrate the Laplace transform of a given function we say we see in the theorem that when we integrate the Laplace transform of a given function $f(t)$. Let us denote the Laplace transform of $f(t)$ by $F(u)$. Then what we get is that if the function $f(t)$ is divided by t we get the Laplace transform of $f(t)$ by t equal to integral s to infinity $F(u) du$. So, this theorem tells us that if $f(t)$ satisfies the conditions of the existence theorem and moreover limit of $f(t)$ over t as t goes to 0 from the right exist. Then we have Laplace transform of $f(t)$ over t equal to integral over s to infinity $F(u) du$ where u is greater than γ and $\lim_{t \rightarrow 0^+} f(t) = F(u)$. So, let us see what is the value of integral s to infinity $F(u) du$ integral s to infinity $F(u) du$ integral s to infinity $F(u) du$ when we put the value of $F(u)$ here becomes integral s to infinity integral 0 to infinity e^{-ut} to the power minus u into $f(t) dt du$.

(Refer Slide Time: 39:23)

$$\begin{aligned}
 &= \int_0^\infty \left(\int_s^\infty e^{-ut} du \right) f(t) dt = \int_0^\infty \left[\frac{e^{-ut}}{-t} \right]_s^\infty f(t) dt \\
 &= \int_0^\infty \frac{e^{-st}}{t} f(t) dt = \int_0^\infty e^{-st} \left(\frac{f(t)}{t} \right) dt \\
 &= L\left(\frac{f(t)}{t}\right).
 \end{aligned}$$

And, which is equal to integral 0 to infinity integral we change the order of integration here. So, integral 0 to infinity integral s to infinity e^{-ut} into $f(t) dt du$ which is equal to integral 0 to infinity integral of e^{-ut} is e^{-ut} over $-t$ because they are integrated here with respect to u and the limits are s and infinity into $f(t) dt$.

Now, when t goes to infinity, because u is greater than γ and γ in the existence theorem it can be taken to be positive. So, e^{-ut} goes to 0 as t goes to infinity and when we put the lower limit, the value of this expression becomes e^{-st} .

to the power minus $s t$ over t . And so we get the right hand side as integral 0 to infinity e to the power minus $s t$ over t into $f t$ $d t$ which can be written in the form of the Laplace transform of $f t$ over t that is integral 0 to infinity e to the power minus $s t$ into $f t$ over t $d t$. So, we get the right hand side this equal to L of $f t$ over t .

(Refer Slide Time: 40:35)

Example. Find $L\left(\frac{\sinh at}{t}\right)$.

Solution. We know that $L(\sinh at) = \frac{a}{s^2 - a^2}$.

Therefore, in view of above theorem

$$L\left(\frac{\sinh at}{t}\right) = \int_s^\infty \frac{a}{u^2 - a^2} du$$

$$= \frac{1}{2} \int_s^\infty \left(\frac{1}{u-a} - \frac{1}{u+a} \right) du$$

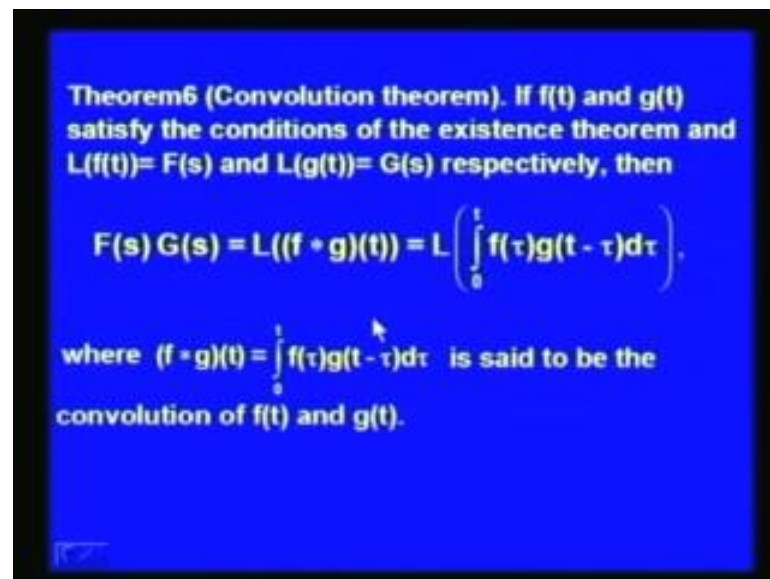

$$= \frac{1}{2} \ln \left(\frac{s+a}{s-a} \right), \quad s > |a|.$$

Let us, take an example based on this theorem let us find the Laplace transform of $\frac{\sinh at}{t}$. We know from our previous lecture on Laplace transformation that Laplace transform of $\sinh at$ is $\frac{a}{s^2 - a^2}$. Therefore in view of the above theorem Laplace transform of $\frac{\sinh at}{t}$ will be equal to integral s to infinity Laplace transform of $\sinh at$ which is $\frac{a}{u^2 - a^2}$. So, we integrate $\frac{a}{u^2 - a^2}$ with respect to u and substitute the limits as an infinity to get the desired Laplace transform.

So, when we integrate in order to integrate this we break it into partial fractions and the partial fractions are $\frac{1}{2} \left(\frac{1}{u-a} - \frac{1}{u+a} \right)$, when we integrate this with respect to u , what we will get $\frac{1}{2} \left(\ln |u-a| - \ln |u+a| \right)$. And the limits of integration are s to infinity, when we would like to use the upper limit that is u goes to infinity $\ln |u-a| - \ln |u+a|$ will tend to infinity minus infinity. So, we break we write it in the form of $\ln \left| \frac{u-a}{u+a} \right|$. And dividing by u then it can be written as $\ln \left| \frac{1-a/u}{1+a/u} \right|$, so when u will tend to infinity it will tend to $\ln 1$ which will go to 0.

So, this expression after integration as u goes to infinity will tend to 0 and when we put the lower limit the value of this integral will come out to be half of $\ln s$ plus a over s minus a whenever s is greater than $\text{mod of } a$, the condition that s is greater than $\text{mod of } a$ comes from here. Because $\ln s$ plus a exists when s is greater than $\text{mod of } a$ and $\ln s$ minus a exists when s is greater than a , so s must be greater than $\text{mod of } a$.

(Refer Slide Time: 42:44)

Now, we study a very important property of the Laplace transforms which is known as the convolution theorem. If we know the Laplace transform of two functions $f(t)$ and $g(t)$, we can find the Laplace transform, then wants to know what is means the Function whose when Laplace transform gives us the product of the Laplace transform of $f(t)$ and $g(t)$. It will turn out that that function if we call that function as $f * g$ is nothing but the convolution of $f(t)$ and $g(t)$ and the convolution of $f(t)$ and $g(t)$ which we will denote $f * g$ is defined as $\int_0^t f(\tau)g(t - \tau)d\tau$. This theorem is extensively use in the study on integral equations and many other problems of engineering, so it has been lots of applications.

So, let us assume that $L(f(t)) = F(s)$ $L(g(t)) = G(s)$ and $f(t)$ and $g(t)$ satisfy the conditions of the existence theorem. Then we see that $F(s)G(s)$, the product of Laplace transform of $f(t)$ and $g(t)$ is nothing but the Laplace transform of the convolution of f and g that is $f * g$ and $f * g$ is by definition $\int_0^t f(\tau)g(t - \tau)d\tau$. This $f * g$ satisfy the evolution of $f(t)$ and $g(t)$.

(Refer Slide Time: 44:25)

Proof.

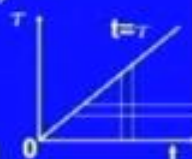

$$L((f * g)(t)) = \int_0^{\infty} e^{-st} \left(\int_0^t f(\tau)g(t - \tau)d\tau \right) dt.$$

$$= \int_0^{\infty} \int_{\tau}^{\infty} e^{-st} f(\tau)g(t - \tau) dt d\tau.$$

(changing the order of integration)

$$= \int_0^{\infty} \int_0^{\infty} e^{-s(t+u)} f(\tau)g(u) du d\tau,$$

where $t + \tau = u.$

Let us, look at the proof of this theorem $L(f * g)(t)$ will be equal to $\int_0^{\infty} e^{-st} \int_0^t f(\tau)g(t - \tau) d\tau dt$ by definition is $\int_0^{\infty} \int_{\tau}^{\infty} e^{-st} f(\tau)g(t - \tau) dt d\tau$. So, now we want to change the order of integration here, the inner integral with respect to τ and the outer integral is with respect to t . So, let us look at $t - \tau$ plane based our real this horizontal axis is t axis the vertical axis is τ axis and this is the line $t = \tau$.

So, here we are integrating first with respect to τ and then with respect to t τ varies from 0 to t so; that means, we are taking a vertical strip and the region over which we are integrating is this 1. So, when we are integrating first with respect to τ and τ varies from 0 to t , it means that we are taking a vertical strip over this region. So, because for this vertical strip τ is from 0 to $\tau = t$ and t varies from 0 to infinity in this part of the plane.

So, when we want to change the limits of integration the order of integration, then now we will have to take a horizontal strip here. So, this we take the horizontal strip arbitrary horizontal strip in this area and then the limits of integration for t first we shall write the limits of integration for t . So, t varies from τ to infinity and then we write the limits of integration for τ , so τ varies from 0 to infinity. So, we change the order of integration here, first we have the limits of integration for t varies from τ to infinity and then we have the limits of integration for τ varies from 0 to infinity.

Now, let us put $t - \tau$ equal to u here when we put $t - \tau$ equal to u here, the limits of integration that is t varies from τ to infinity change to t varies from 0 to when u varies from 0 to infinity and we get the integrate as $e^{-s(t-\tau)} f(\tau) g(t-\tau)$. The limits of integration for u are 0 infinity for τ they are again 0 infinity. And here, we can separate the variables τ and u we can write $e^{-s(t-\tau)} f(\tau) g(t-\tau)$ as $e^{-s\tau} f(\tau) e^{-su} g(u)$. So, let us group the terms which depend on τ and which and the terms which depend on u and separate the two integrals we can we have the following.

(Refer Slide Time: 47:17)

$$\begin{aligned}
 &= \left(\int_0^{\infty} e^{-s\tau} f(\tau) d\tau \right) \left(\int_0^{\infty} e^{-su} g(u) du \right) \\
 &= L(f(t)) L(g(t)) \\
 &= F(s) G(s).
 \end{aligned}$$

Example. Find $L^{-1}\left(\frac{s^2 + s}{(s^2 + 1)(s^2 + 2s + 2)}\right)$.

Solution. We may write

$$L^{-1}\left(\frac{s^2 + s}{(s^2 + 1)(s^2 + 2s + 2)}\right) = L^{-1}\left(\frac{(s+1)}{((s+1)^2 + 1)} \cdot \frac{s}{(s^2 + 1)}\right).$$

We have we the last double integral may be equal to is then equal to the product of these simple integrals, integral 0 to infinity $e^{-s\tau} f(\tau) d\tau$ and then integral 0 to infinity $e^{-su} g(u) du$. This integral is the Laplace transform of $f(t)$ and this integral is Laplace transform of $g(t)$ and which is equal to $F(s)$ into $G(s)$. Let us, apply this convolution theorem to find the inverse Laplace transform of the Function $s^2 + s$ over $s^2 + 1$ into $s^2 + 2s + 2$. The inverse Laplace transform of this may be this Function of s may be regarded as product of two functions s over $s^2 + 1$ s over $s^2 + 1$ and then another 1 as $s + 1$ over $s^2 + 2s + 2$.

So, we can write the inverse Laplace transform of the given function s equal to L^{-1} of $s + 1$ over $(s + 1)^2 + 1$ into s over $s^2 + 1$. So, 1 we will

take as $F(s)$ and other Function of s will take as $g(s)$ and then we will be writing L^{-1} inverse of $F(s)$ into $g(s)$ equal to convolution of f and g by the convolution theorem.

(Refer Slide Time: 48:35)

$$\begin{aligned}
 &= L^{-1}\left(\frac{s+1}{((s+1)^2+1)}\right) * L^{-1}\left(\frac{s}{(s^2+1)}\right) \\
 &\quad \text{(by convolution theorem)} \\
 &= (e^{-t}\cos t) * (\cos t) \\
 &= \int_0^t e^{-u} \cos u \cos(t-u) du \\
 &= \frac{1}{2} \int_0^t e^{-u} [\cos t + \cos(2u-t)] du \\
 &= \frac{1}{5} e^{-t} (\sin t - 3\cos t) + \frac{1}{5} (\sin t + 3\cos t).
 \end{aligned}$$

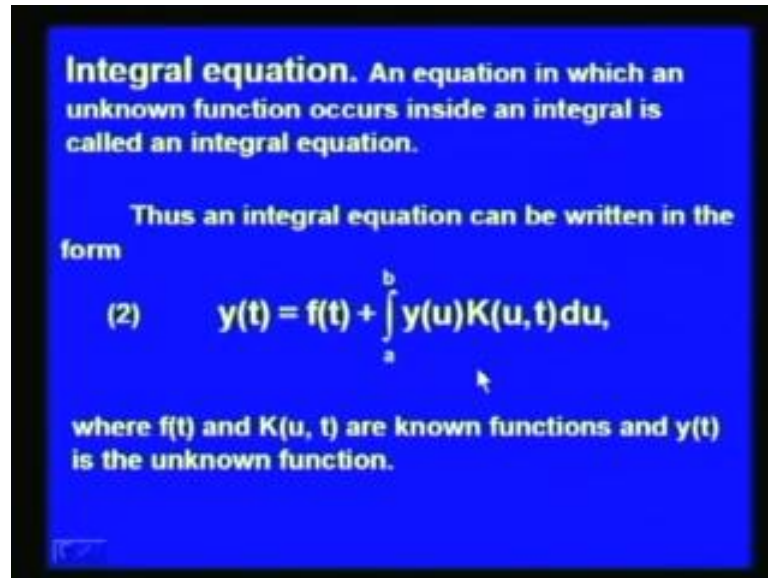

So, we have convolution of f and convolution of g this is L^{-1} of $s+1$ over $s+1$ whole square plus 1 star L^{-1} of s over s square plus 1 this is star denotes the convolution. So, this is $f(t)$ and this is $g(t)$ by convolution theorem. So, now, inverse Laplace transform of $s+1$ over $s+1$ whole square plus 1 using the first shifting theorem with which we have studied in the previous lecture on Laplace transformation gives us $e^{-t} \cos t$. We know that Laplace transform of s over s square plus 1 is $\cos t$.

And then you multiply $e^{-t} \cos t$, then its Laplace transform gives $s+1$ over $s+1$ whole square plus 1. So, inverse Laplace transform of this function of s is $e^{-t} \cos t$ and inverse Laplace transform of s over s square plus 1 we know it is $\cos t$. So, this is equal to integral 0 to infinity $e^{-u} \cos t \cos u$ into $\cos t \cos u$ du .

Now here, we have two functions one is f and another one is g and we write it as integral 0 to t $F(u) g(t-u) du$. So, which function is to be chosen as $F(u)$ and which is to be chosen as $g(u)$ depends on how conveniently we can evaluate this integral, because $f * g$ is always equal to $g * f$ convolution of f and g same as convolution of g and f . So, we are free to choose any function out of these two as f and the other one as g . And this,

Further equal to half of integral 0 to t e to the power minus u cos t plus cos 2 u minus t d u which is equal to after integration we get 1 by 5 e to the power minus t sin t minus 3 cos t plus 1 by 5 sin t plus 3 cos t.

Integral equation. An equation in which an unknown function occurs inside an integral is called an integral equation.

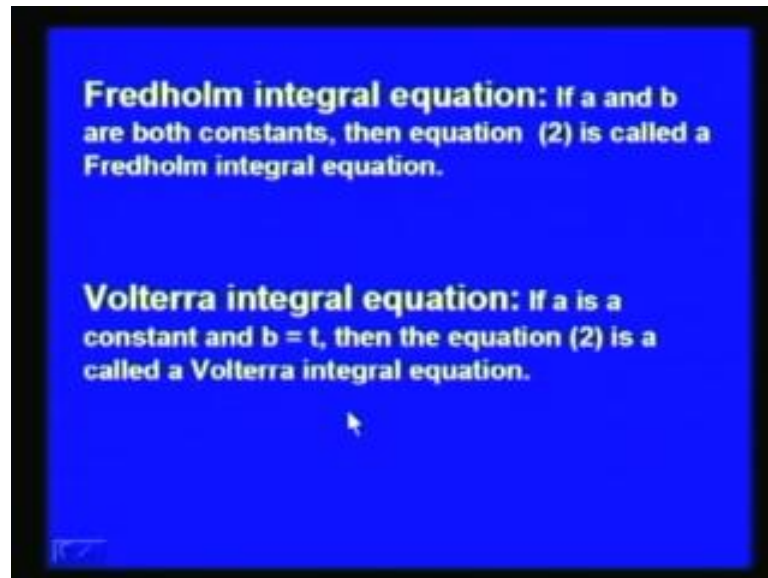

Thus an integral equation can be written in the form

$$(2) \quad y(t) = f(t) + \int_a^b y(u)K(u, t) du,$$

where $f(t)$ and $K(u, t)$ are known functions and $y(t)$ is the unknown function.

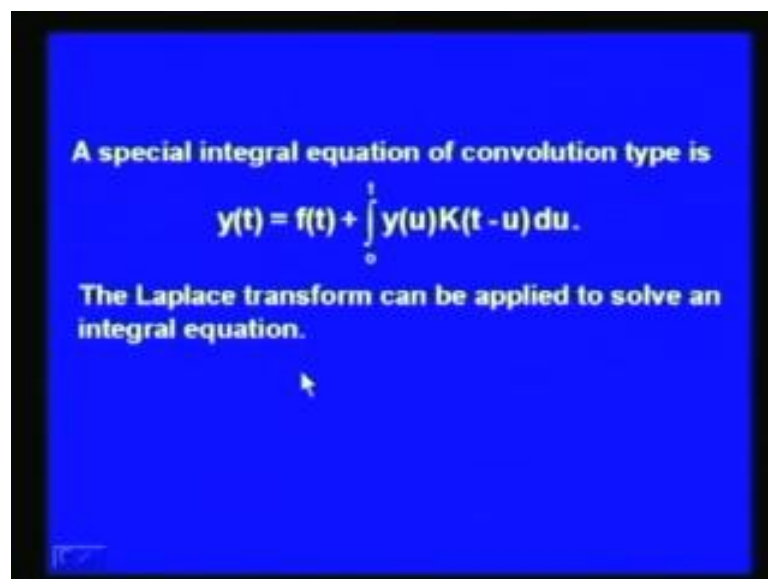

Now, we shall be applying this convolution theorem to find a solution of an integral equation. Let us, see what is an integral equation an integral equation is an equation in which an unknown function occurs inside an integral, thus an integral equation may be written as $y(t) = f(t) + \int_a^b y(u)K(u, t) du$, where $f(t)$ and $K(u, t)$ are known functions and $y(t)$ is the unknown Function $K(u, t)$ is called the kernel function.

(Refer Slide Time: 51:18)

Now, this if a and b are both constants then the integral equation 2 is called a Fredholm integral equation and if a is a constant b and b equals the variable t then the equation 2 is known as a Volterra integral equation.

(Refer Slide Time: 51:37)

Now, a special integral equation of convolution type is when Volterra integral equation where you take a equal to 0. So, $y(t)$ is equal to $f(t)$ plus integral 0 to t $y(u)$ into $k(t-u)$ du here we take $k(t-u)$ as $k(t-u)$ and a as 0. So, it is a special kind of Volterra

integral equation we are going to find the Laplace transform we are going to find a solution of an equation of this type.

(Refer Slide Time: 52:07)

Example. Solve $y'(t) = t + \int_0^t y(t-u) \cos u \, du$, $y(0) = 4$.

Solution. Taking Laplace transform of both sides

$$sy(s) - 4 = \frac{1}{s^2} + L(y(t))L(\cos t)$$

$$= \frac{1}{s^2} + \bar{y}(s) \frac{s}{s^2 + 1}$$

$$\Rightarrow \bar{y}(s) = \frac{(s^2 + 1)(1 + 4s^2)}{s^5} = \frac{4}{s} + \frac{5}{s^3} + \frac{1}{s^5}$$

Hence, $y(t) = 4 + \frac{5}{2}t^2 + \frac{1}{24}t^4$

So, let us solve the differential integral equation $y'(t) = t + \int_0^t y(t-u) \cos u \, du$. So here, $f(t)$ is equal to t and $g(t-u)$ is equal to $\cos u$ and instead of y here, we have $y'(t)$, $y(t)$ is the unknown function of t , which we are given the initial condition that $t = 0$ y takes the value 4.

So, let us take the Laplace transform of on both sides of this integral equation L of $y'(t)$ is equal to $s \bar{y}(s) - y(0)$, $y(0)$ is equal to 4 Laplace transform of t is $1/s^2$ and then the Laplace transform of $\int_0^t y(t-u) \cos u \, du$ if we take $f(u) = \cos u$ and $g(t-u) = y(t-u)$, then we know by convolution theorem that Laplace transform of $\int_0^t y(t-u) \cos u \, du$ is equal to Laplace transform of $y(t)$ into Laplace transform of $\cos t$.

So, the right hand side of this equation becomes $1/s^2 + \bar{y}(s) \frac{s}{s^2 + 1}$ Laplace transform of $y(t)$ is $\bar{y}(s)$ and Laplace transform of $\cos t$ is $s/(s^2 + 1)$. Now, we solve this equation for the value of $\bar{y}(s)$ it turns out that $\bar{y}(s)$ is equal to $(s^2 + 1)(1 + 4s^2)/s^5$. When we break into its partial fraction, we get the partial fraction as $4/s + 5/s^3 + 1/s^5$. Now, we take the inverse Laplace transform of this equation, inverse Laplace transform of $\bar{y}(s)$ is $y(t)$. And then the right hand side when we take the inverse Laplace transform we get $4 + 5/2 t^2 + 1/24 t^4$.

into t^2 by 2, and then t to the power 4 by 4 factorial. So, we get $y(t)$ equal to $4 + 5$ by $2t^2$ plus 1 by 24 into t to the power 4.

Now, in our lecture today, we have consider some of the properties of the Laplace transforms like Laplace transform of derivatives and integrals and then the differentiation and integration of Laplace transforms and the convolution theorem. In my next lecture we will be doing some more properties of the Laplace transforms like the second shifting theorem which refers to the shifting on the s axis. If you recall the first shifting theorem refers to the shifting on the t axis the second shifting theorem refers to the shifting of the s axis.

And then in the theorem on shifting on the s axis that is second shifting theorem we shall be making use of a special function known as unit step function which is also called as Heaviside's function. And we will be discussing Dirac delta function which is also known as an impulse function.

So, unit step function and Dirac delta functions have very special importance and the in the study of problems that occur in mechanical and electrical engineering. So, we will be looking some of the applications of those functions in the problems of electrical and mechanical engineering. And we will also be considering Laplace transform of periodic function. So, all these we will be covering in our next lecture.

Thank you.
