Module - 05
Water supply Distribution system and Plans
Lecture - 24
Pipes, Joints, Meters and SCADA Systems

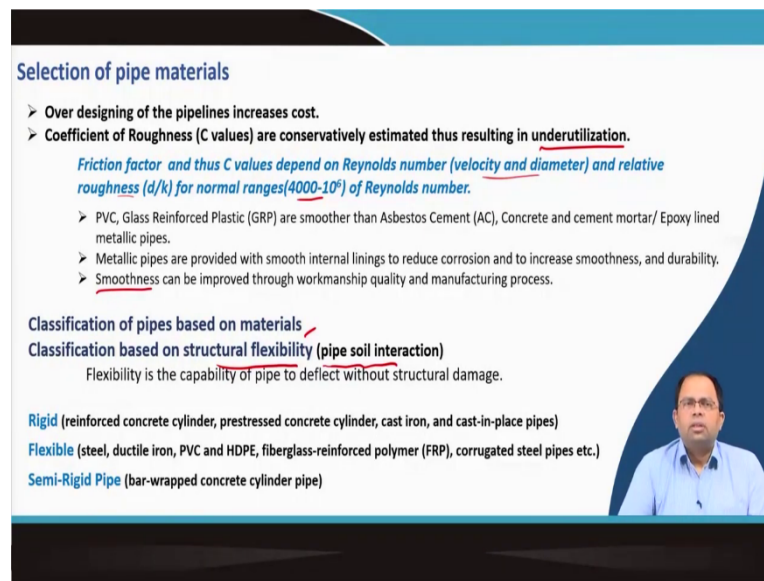

Welcome back. In lecture 24, we will talk about Pipes, Joints, Meters and SCADA systems.

(Refer Slide Time: 00:38)

The different concepts that we will cover include selection of pipe materials, classification of pipes based on materials, checklist for selection of pipe materials, pipes different kinds of pipes and joints, water meters, and then we will talk about telemetry and SCADA systems.

(Refer Slide Time: 01:00)

Selection of pipe materials

- Over designing of the pipelines increases cost.
- Coefficient of Roughness (C values) are conservatively estimated thus resulting in underutilization.

Friction factor and thus C values depend on Reynolds number (velocity and diameter) and relative roughness (d/k) for normal ranges (4000-10⁶) of Reynolds number.

- PVC, Glass Reinforced Plastic (GRP) are smoother than Asbestos Cement (AC), Concrete and cement mortar/ Epoxy lined metallic pipes.
- Metallic pipes are provided with smooth internal linings to reduce corrosion and to increase smoothness, and durability.
- Smoothness can be improved through workmanship quality and manufacturing process.

Classification of pipes based on materials

Classification based on structural flexibility (pipe soil interaction)

Flexibility is the capability of pipe to deflect without structural damage.

Rigid (reinforced concrete cylinder, prestressed concrete cylinder, cast iron, and cast-in-place pipes)

Flexible (steel, ductile iron, PVC and HDPE, fiberglass-reinforced polymer (FRP), corrugated steel pipes etc.)

Semi-Rigid Pipe (bar-wrapped concrete cylinder pipe)

Selection of pipe materials

So, from our earlier lectures, we have already discussed that the selection of pipe material is based on many factors. And the selection of pipe materials has to be carefully done as over designing of pipelines increases the cost. The coefficient of roughness or the C values that are conservatively estimated results in underutilization. Then we end up designing infrastructure which is not required or pipelines which are over designed.

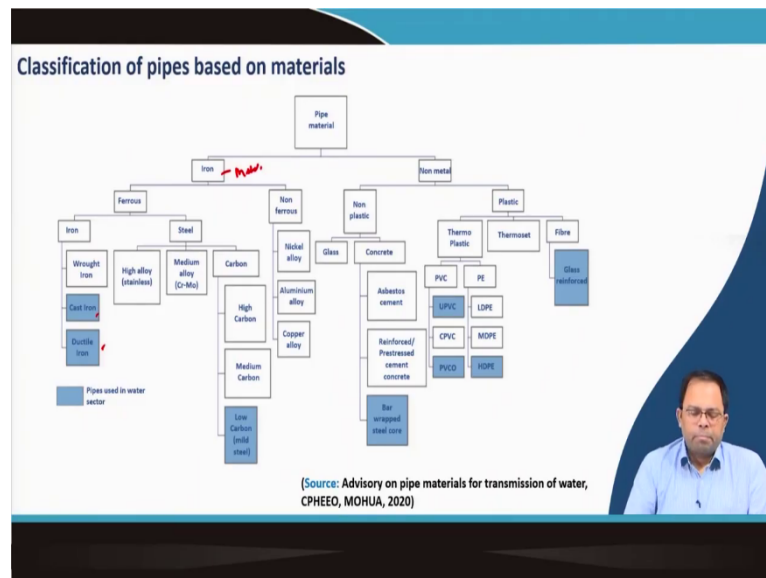

So, friction factor and thus C values depends on Reynolds number which we have learned earlier which depends again on velocity, diameter, and viscosity, and density of liquid and so on. So, particularly, velocity and diameter are important for pipelines. And relative roughness for normal ranges of Reynold number that is 4000 and up.

So, these are the ones which primarily determines the kind of pipe materials to be used. The different materials are PVC, glass reinforced plastic, GRP, asbestos cement concrete, and cement mortar epoxy lined metallic pipes. Metallic pipes are provided with smooth internal linings to reduce corrosion and to increase smoothness, and durability. They are sometimes lined with concrete which actually increases the smoothness of those particular pipes. And smoothness can be improved through workmanship quality and manufacturing process. So, smoothness or roughness is very important for pipe selection. So, pipes could be classified

based on the materials or it could be classified based on their structural flexibility. Structural flexibility is important considering the interaction between the soil and the pipeline.

Flexibility is the capability of the pipe to deflect without structural damage. So, there are 3 kinds of pipelines, one is rigid, one is flexible and then there are semi-rigid pipes. Rigid pipelines are made of RCC, reinforced concrete cylinders, pre-stress concrete cylinders, cast iron, cast in place pipes. Whereas, flexible pipes are steel pipes, ductile iron, PVC, HDPE, glass-reinforced polymer, all these fiberglass reinforced polymer, corrugated steel pipes. And then there are semi rigid pipes as well. So, either we can classify based on the rigidity or we can classify based on the materials.

(Refer Slide Time: 03:55)

Classification of pipes based on materials

There are different kind of materials to choose from. It can be metallic or non-metallic, ferrous or non-ferrous, alloys, plastics and many more as shown in Figure 1. So, we need to understand what is the pros and cons, and what are the ratings of the different kinds of pipes, check if it matches for thickness, size, test pressure such as internal pressure, external pressure, and so on. So, based on that we will choose the pipes.

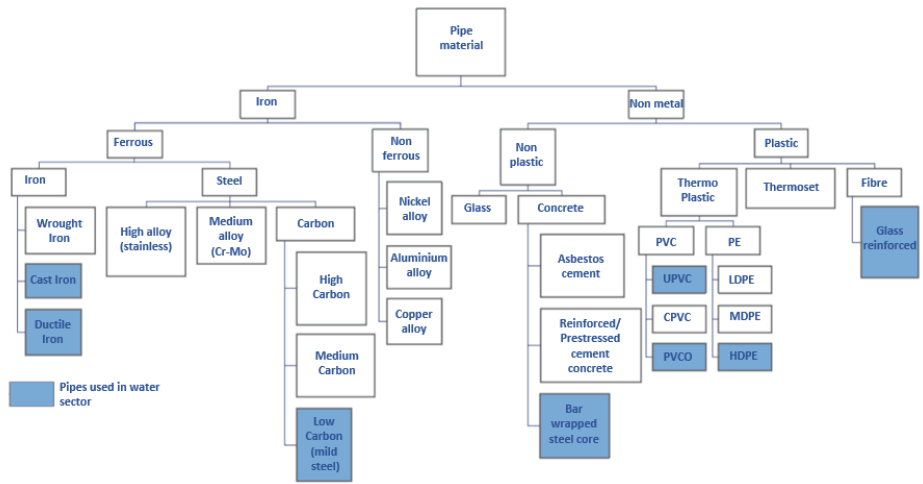

Figure 1 Classification of pipes based on materials

(Refer Slide Time: 05:45)

Check List for selection of pipe materials

Sl.no.	Attribute	PVC	AC	CI	DI	MS	PSC	GRP	HDPE	HUME	GI	OTHERS	Remarks if any
1	Impact of Human Health (Adverse / Favourable / Neutral)												
2	Hydraulic smoothness (C Value)												
3	Structural strength for external loads and diameter stiffness												
4	Stress calculations and factor of safety consideration in determining strength												
5	Basic material mechanical properties and ageing analysis												

(Source: Advisory on pipe materials for transmission of water, CPHEEO, MOHUA, 2020)

- Strength to sustain internal pressure
- Ease in handling, transportation and storage
- Capacity to withstand damage in handling and maintenance
- Resistance to internal corrosion
- Resistance to external corrosion
- Resistance to heat/sunlight and durability under all-weather condition
- Resistance to rodent attack/pilferage
- Sustainability in Black Cotton Soil
- Reliability and effective joints
- Reactivity of pipe material with water at different temperature and pressure
- Capable to absorb surge pressure (water hammer)
- Ease in maintenance and repairs
- Use experience
- Durability (Sustainable trouble free maintenance)
- Consumer satisfaction
- Resistance to tampering by anti-social elements
- Economy
- Availability of specials
- Availability of skilled personnel for installation & maintenance
- Behaviour of pipe line — likelihood of interruptions due to leakage, bursting etc. and time for repairs
- Recommended size range for Rising Main Gravity Main Distribution Network House Service Connection

Checklist for selection of pipe materials

Decision to select pipe materials depend on a number of things. Apart from the diameter, material, roughness, there are government mandated criterial to be met. Government of India, on its advisory on materials for transmission of water by CPHEEO, and ministry of housing and urban affairs, have listed these different points which has to be considered when we choose a pipe material. So, you can understand the importance of determination of pipe material when we design a water supply network.

So, first of all we have to look into impact on human health of this particular material, hydraulic smoothness, structural strength of external loads and diameter stiffness, stress calculation and factor of safety considering consideration strength, basic material, mechanical properties and ageing analysis. Then, strain to sustain internal pressure, ease in handling transportation and storage which are site specific. That means, certain pipes are suitable for certain areas because there may not be space to store them or there may be issues with transporting them. So, you cannot use very heavy pipes and so on. Capacity to withstand damage in handling and maintenance, resistance to internal corrosion, resistance to external corrosion, resistance to rodent attack, reliability effectiveness of joints. Use experience, ease in maintenance and repairs, then durability, consumer satisfaction, economy, resistance to tampering by social elements, then availability of skilled personnel for installation and maintenance are some of the factors to be considered.

So, not all can be considered for in every case, but wherever possible we will look into all the factors and then make a decision on which pipe to use or which material to choose from.

(Refer Slide Time: 08:13)

Pipes and joints

IS 1536-1967 mentions three categories

	Test pressure(kg/cm ²)	Working pressure(kg/cm ²)
Class LA	35	12
Class A	35	18
Class B	35	20

Cast iron pipes

- Widely used in water supply schemes
- Long life of hundred years
- Corrosion resistant
- Molded from best pig iron
- Both horizontal and vertical mould
- Coal Tar coating to prevent corrosion
- Length: 2.5 to 5.5 meter
- Cannot withstand high internal pressure
- Joined together by means of bell and spigot
- Threaded rod flanged joints

(Source: <http://www.metals-china.com/introduction-about-high-strength-ductile-iron-pipe-cast-iron-pipe.html>)

Pipes and joints

Now, let us look at the different kinds of common pipes and joints. Cast iron pipes and their classifications are specified in the IS 1536 to 1967 which shows the different categories of

pipes. It basically has 3 classes of pipes, class 3A, class A and class B. Each class can take care of different pressure, like working pressure for these 3 classes are 12, 18, 20, whereas, test pressure is all same. That means for a small period of time it can all withstand 35 kg per centimeter square of pressure, but for a longer period ratings that these are different for each class.

Cast iron pipes are very widely used in water supply schemes. These are very common as they have long life, are corrosion resistant and are molded from pig iron. And the molds are both horizontal and vertical. A coal tar coating is provided to prevent corrosion. Typical lengths are around 2.5 to 5.5 meter.

They cannot withstand high internal pressure, but they can withstand outside external pressure. And they are joined using bell and spigot joints and or threaded and flanged joints.

(Refer Slide Time: 09:42)

Spigot and socket joint

- Lead as filling material
- Used in cast iron pipes
- Spigot end cast into the bell end
- Yarn of hemp is wrapped around the spigot end

Wrought iron pipes

- Manufactured by rolling flat plates of metal and welding the edges
- Lighter compared to cast iron
- Easily cut, threaded and worked
- Less durable

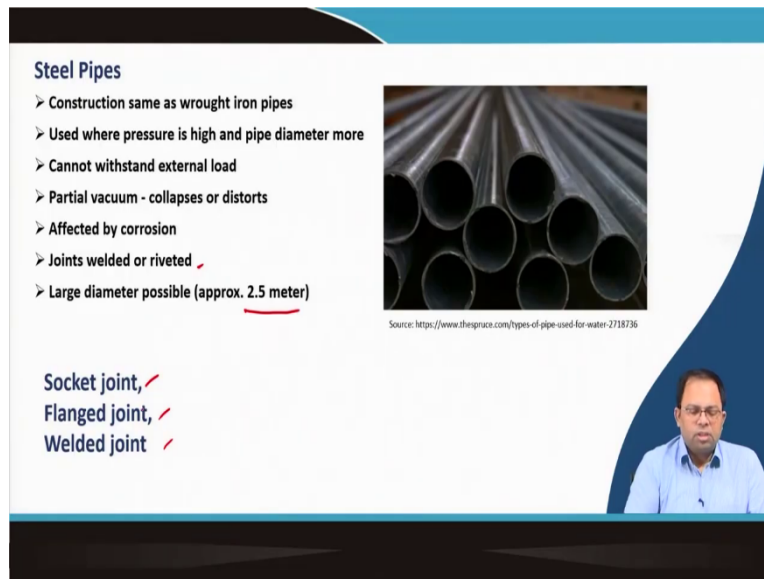

Source: <https://civilseek.com/types-of-pipes/>

Spigot and socket joint

Hemp or yarn is wrapped around the spigot end and it is cast into the bell end. So, this is how we actually connect the different pipelines. Lead is used as a filling material. Mostly used for cast iron pipes, spigot end cast into the bell end, and yarn of hemp is wrapped around this spigot end.

So, similar to cast iron pipes, we also have got wrought iron pipes which are almost similar, but these are manufactured by rolling flat plates of metal and welding the edges. So, instead of the previous kind of cast iron pipes where it was put into molds, here we actually have flat sheets which is actually rolled and then welded up. And these are lighter compared to cast iron. They can be easily cut, threaded, and worked, but they are also less durable.

(Refer Slide Time: 11:00)

Steel Pipes

- Construction same as wrought iron pipes
- Used where pressure is high and pipe diameter more
- Cannot withstand external load
- Partial vacuum - collapses or distorts
- Affected by corrosion
- Joints welded or riveted ✓
- Large diameter possible (approx. 2.5 meter) ✓

Socket joint, ✓
Flanged joint, ✓
Welded joint ✓

Source: <https://www.thepruce.com/types-of-pipe-used-for-water-2718736>

Steel pipes

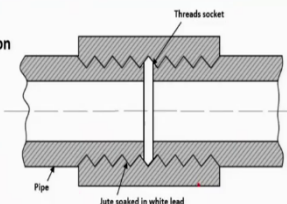

The construction of steel pipes is similar to wrought iron pipes. And this is used where internal pressure is high and pipe diameter is required is more. These pipes cannot take high external loads, so they are not suitable for taking load from above. We can make flat sheets, roll it, and weld it.

And in case a partial vacuum is created, sometime these kind of pipe collapses. And they are affected by corrosion to some extent. The joints are either welded or riveted joints and we are able to have large diameter pipes. 2.5-meter diameter pipelines are even possible.

(Refer Slide Time: 12:01)

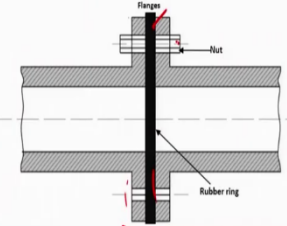

Screwed Joint

- Connects small diameter cast iron, wrought iron and galvanized pipes.
- Pipe threaded on outside.
- Coupling has threads on inner side.
- Hemp yarn.

Flanged joint

- Temporary pipelines.
- Flanges on both ends.
- Hard rubber washer between flanges are bolted to make it watertight.
- Cannot withstand vibrations.

Jute soaked in white lead

Flanged joints

In flanged joints, both pipes have got a sort of collar. And then there is a screw which connects these two pipes, and in between we give a washer, so that it becomes watertight. So, but as you can understand that it depends on the number of screws that are fitted and in case there is vibration, the screws can come loose or there may be gaps which may form over there. So, that is why these pipes are good for temporary cases or in cases where there is absolutely no vibration.

Screwed joints

In case of screwed joints, we have a separate piece which connects small diameter cast iron, wrought iron, and galvanized pipes. And the pipes are threaded on the outside and this coupling has got threads on the inside and we just rotate the pipes and fit them into the coupling from both ends. And we can also use hemp and yarn in the gaps so that this gap becomes watertight. So, this is how screwed joints and flanged joints are done.

(Refer Slide Time: 13:14)

Concrete pipes

- Precast/ cast-in-situ
- Plain concrete up to 60 cm diameter above which it is reinforced
- RCC pipes having steel bar and mesh reinforcement – usual pouring of concrete, tamping and curing of pipes having fabricated reinforcement hand cast by centrifugal methods
- Reinforcement - Welded Steel cylinder with High Tension wire. Sometimes mesh reinforcement used.
- Normally 1: 2: 2 concrete mix
- Thickness 25 to 65 mm
- Diameter 10 to 120 cm
- Pre-stressed concrete pipes 1200 mm

Advantages and disadvantages

- *Least coefficient of thermal expansion*
- *Does not collapse under traffic load*
- *Heavyweight.*
- *Difficult to repair.*

(Note: The slide also features a small video inset of a man in a blue shirt in the bottom right corner.)

Concrete pipes

The concrete pipes are mostly precast or it could be cast in situ, but precast is usually preferred. They can be plain concrete or reinforced concrete pipe. Plain concrete pipe up to a diameter of 60 centimeter or 2 feet and beyond that we have to go for reinforcement. Reinforcement can be of different kind. It could be steel bars with mesh reinforcement. Then concrete is poured, and then tamping and curing is done. We can cast using centrifugal methods. It could also be a welded steel cylinder with high tension wire and also with mesh reinforcement. And the concrete mix is usually 1: 2: 2. Thickness of this kind of pipe is 25 to 65 mm and diameter up to 120 cm. So concrete pipe diameter can start from 10 cm centimeters and pre-stressed pipes can go up to a 1200 millimeter or 120 centimeters.

These kinds of pipes have a lot of advantages. They are able to take a lot of external load because these are pretty thick. These pipes has the least coefficient of thermal expansion. So, thermal expansion is not that big an issue. It does not collapse under traffic load, but the problem is these are of heavy weight. These need to be transported using lorries which is difficult in many places and these are difficult to repair as well.

(Refer Slide Time: 14:55)

Concrete pipes

According to IS 458-1971:

	Test pressure(kg/cm ²)	Diameter	Use
Class P1	2	80-1200	Design pressure gravity mains
Class P2	4	80-600	1.33 kg/cm ² and pumping mains <u>2</u> kg/cm ²
Class P3	6 ✓	80-400 ✓	

Source: <http://www.traceyconcrete.com/site/pipes/ogee-drainage-pipes> Source: <https://theconstructor.org/concrete/design-concrete-pipes-sewers/1765/>

So, there are again 3 classes of pipe as given in IS 458-1971, class P1, P2 and P3. So, test pressure is around 2 kg per centimeter square or 4 or 6 kg per centimeter square and design pressure is 1.33 kg per centimeter square, and for gravity mains and for pumping mains around 2 kg per centimeter square.

So, diameter supported is 80 to 1200 for P1, 80 to 600 for P2 and for P3 80 to 400. So higher the test pressure, lesser is the diameter. If the internal pressure is high it is better to opt for steel pipes and other pipes.

(Refer Slide Time: 15:56)

Cement lined cast iron pipe

- Lined with cement to protect them against corrosion.
- Lining of 1: 2 cement mortar done centrifugally.
- Thickness from 3 to 6 mm.
- Small coefficient of friction.
- IS 1916-1963 has Class 1-5, with Test pressure ranging from 5-25 kg/cm² and working pressure at 50%.

Asbestos cement pipe

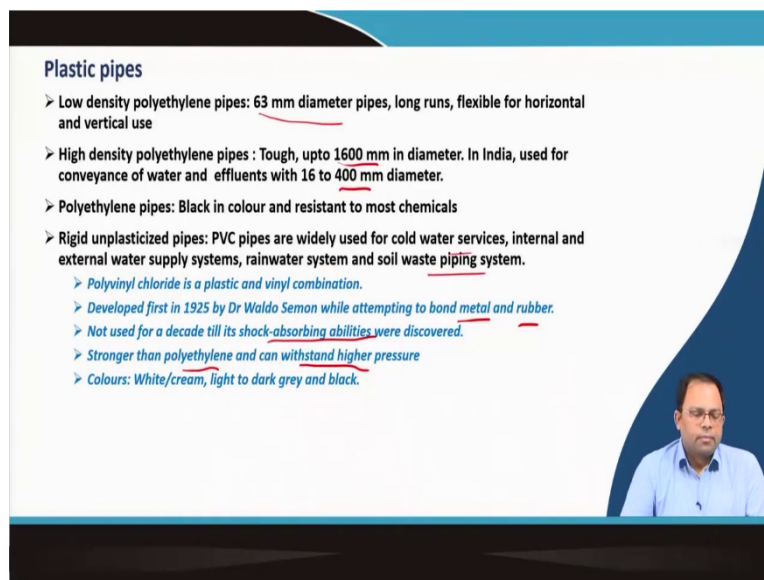

- Mixture of cement and asbestos fibre.
- 50 mm to 1000 mm in diameter. ✓
- 5 kg/cm² to 25 kg/cm² test pressure.

Cement lined cast iron pipes

If we want to get the benefit of both cast iron pipe and a cement pipe, we use cement lined cast iron pipes which actually increases the smoothness of that particular cast iron pipe and also increases its longevity by reducing corrosion. The lining is made of 1: 2 cement mortar, and it is done using centrifugal methods. And thickness is around 3 to 6 mm and friction coefficient is small. The IS 1916-1963 has 5 classes, classes 1 to 5, and test pressure ranging from 5 to 25 kg per centimeter square and working pressure at 50 percent of that; that means, 2 to 12 kg per centimeter square of working pressure. Similarly, we have got asbestos cement pipe, it is a mixture of cement and asbestos fiber 50 to 1000 mm in diameter, 5 kg to 25 kg centimeter square of test pressure.

(Refer Slide Time: 17:08)

Plastic pipes

- Low density polyethylene pipes: 63 mm diameter pipes, long runs, flexible for horizontal and vertical use
- High density polyethylene pipes : Tough, upto 1600 mm in diameter. In India, used for conveyance of water and effluents with 16 to 400 mm diameter.
- Polyethylene pipes: Black in colour and resistant to most chemicals
- Rigid unplasticized pipes: PVC pipes are widely used for cold water services, internal and external water supply systems, rainwater system and soil waste piping system.
 - Polyvinyl chloride is a plastic and vinyl combination.
 - Developed first in 1925 by Dr Waldo Semon while attempting to bond metal and rubber.
 - Not used for a decade till its shock-absorbing abilities were discovered.
 - Stronger than polyethylene and can withstand higher pressure
 - Colours: White/cream, light to dark grey and black.

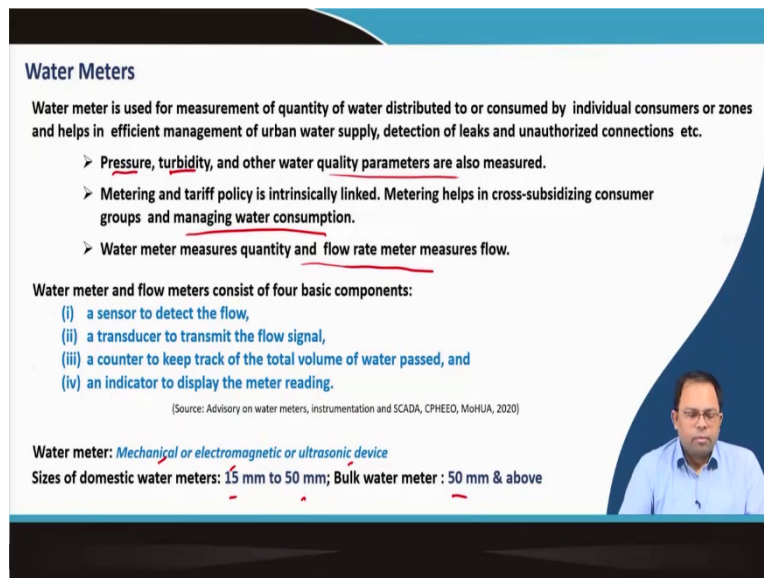

Plastic pipes

Finally, the most common pipes that we find today are the plastic pipes. There are different kinds of plastics such as low-density polyethylene, high-density polyethylene, polyethylene pipes, just simple pipes and rigid unplasticized pipes. Low density polyethylene pipes up to diameters of 63 mm diameter can be flexible and can be used vertically as well. High density polyethylene pipes could be of larger diameter 16 up to 1600 millimeter. But in India we find

only until 400 mm in diameter. Polyethylene pipes are also used. Then, there are PVC pipes which are used for cold water services, internal, external water supply systems, rainwater systems, and soil water piping systems.

There is a history behind the development of PVC pipes. It was initially developed in 1925 by combining plastic and vinyl by Doctor Waldo Semon, when he was attempting to bond metal and rubber. And then, the shock absorbing abilities were discovered for this kind of pipe and they became really popular. These are stronger than polyethylene and can withstand higher pressure and we can find them in usually in white and cream, or light to dark gray colors and even in black color.

(Refer Slide Time: 18:58)

Water Meters

Water meter is used for measurement of quantity of water distributed to or consumed by individual consumers or zones and helps in efficient management of urban water supply, detection of leaks and unauthorized connections etc.

- Pressure, turbidity, and other water quality parameters are also measured.
- Metering and tariff policy is intrinsically linked. Metering helps in cross-subsidizing consumer groups and managing water consumption.
- Water meter measures quantity and flow rate meter measures flow.

Water meter and flow meters consist of four basic components:

- a sensor to detect the flow,
- a transducer to transmit the flow signal,
- a counter to keep track of the total volume of water passed, and
- an indicator to display the meter reading.

(Source: Advisory on water meters, instrumentation and SCADA, CPHEEO, MoHUA, 2020)

Water meter: Mechanical or electromagnetic or ultrasonic device

Sizes of domestic water meters: 15 mm to 50 mm; Bulk water meter : 50 mm & above

Water meters

Next, we will talk about water meters. It is used for measurement of quantity of water distributed or consumed by individual consumers or it could be for zones, and this helps in efficient management of urban water supply, detection of leaks and unauthorized connections. The prime purpose of water meters, both at the zone level and the individual level, is to detect the amount of water that is being consumed.

So, water meters are nowadays changing, from simple water meters to smart water meters. Along with the flow or the quantity of water, they can measure pressure of water, turbidity of

water and some other parameters as well. For this purpose, some of these sensors are inbuilt into the water meter.

Metering and tariff policies are intrinsically linked. Metering helps us to know exactly who is drawing how much water and that helps us to design the tariffs, designing the cross subsidies from one consumer group to another.

So, for managing water consumption, to reduce wastage, to reduce unaccounted water, to design proper tariff policies by a utility provider, we need to have water meters. Water meters are absolutely essential, even though they may reduce a little bit of pressure in the pipeline, but still their benefits outweigh their shortcomings.

A water meter and flow meter consist of 4 basic components, a sensor that detects the flow, a transducer to transmit the flow signal, a counter to keep track of the total volume of water passed and an indicator to display the meter readings. So, water meter could be a mechanical device, an electromagnetic device or an ultrasonic device.

These meters are basically of different sizes, one is 15 mm to 50 mm for individual domestic water supplies, and 50 mm and above for bulk water meters.

(Refer Slide Time: 22:48)

(Source: Advisory on water meters, instrumentation and SCADA, CPHEEO, MoHUA, 2020)

Mechanical Meters

Volumetric Meters
Directly measure the volume of flow.
Positive displacement meters that use a rotating cylindrical piston to measure 'packets' of water.
Rotary Piston Meters

Inferential Meters
Infer the volumetric flow rate from the velocity of the water.
Jet meters use an impeller with radial vanes (also called a fan wheel).
Single or multiple flow streams or jet moves the impeller.
Woltman meter uses an impeller with helical vanes like a fan or boat's propeller.
Single Jet Meters
Multijet Meters
Woltman Meter

Electromagnetic Meters
Magnetic field is created across the pipe. Movement of water induces a voltage while moving through magnetic field which is detected by electrodes in the body of the meter. Voltage is directly proportional to the flow velocity.
Domestic Electromagnetic meter DN15 to DN40
Bulk Electromagnetic meter DN50 to DN300

Ultrasonic Water Meters
Transit Time Ultrasonic Flow Meters
Utilizes the properties of sound waves passing through moving water.
Doppler Ultrasonic Flow meters
Measure change in the frequency of a sound wave when it is reflected back from a moving object.
Domestic Ultrasonic Meter DN15 to DN40
Bulk Ultrasonic Meter DN50 to DN300
Transit time ultrasonic flow meters: Sound waves slow down when moving through the water against the flow, and speed up when they move with the flow.

Next we will discuss the different types of meters. The first one is a mechanical meter. There are two kinds of mechanical meter, one is a volumetric one and the other is an inferential one. The volumetric one directly measures the volume of flow of water. These are basically the rotary piston meters. There is a rotary piston inside, so positive displacement happens inside and a rotating cylindrical piston measures the packets of water, how many packets of water is actually going through that. And from each packet we know the volume of water in each packet and we can determine the total quantum of water that is being passing. So, this is a mechanical system which is utilized to measure the flow.

Then, there are inferential meters which are of 3 kinds, one is a single jet meter, multijet meter and a Woltman meter. Instead of measuring the quantity or the volume of water, it measures the flow rate and the velocity of water. Based on velocity and flow rate it can determine what amount of water is passed by multiplying with the diameter of the pipeline. These kind of meters have got an impeller with radial veins which is also called a fan wheel and there would be single flow of water inside on this fan wheel which makes it rotate. And when it rotates, based on the speed of rotation, we can determine what is the speed of flow of water, which could either be a single jet of water or there could be multiple jets of water which rotates. Accordingly, you get single jet meter and multijet meter.

Woltman meter measures an impeller with helical veins like a fan or a boats propeller which is a little different from the other two meters.

Other than mechanical meters, we have electromagnetic meters and the domestic electromagnetic meters are DN 15 to DN 40, depending on the size and bulk electromagnetic meters starts from DN 50 to DN 300. Electromagnetic or magnetic field is created inside the pipe, and when water moves inside the pipe, it induces a voltage because it is moving through a magnetic field which could be detected by the electrodes in the body of the meter. This voltage generated by the flow of water is actually proportional to the flow velocity. Based on that flow velocity we can now determine the quantum of water present.

We have got ultrasonic water meters making use of sound waves. These are of two types: a transit time ultrasonic flow meter and a doppler ultrasonic flow meter. The sound waves whenever it moves in water, if it moves in the direction of water, it will move faster, if it

moves in the opposite direction of water it will become slower. And so, that time taken by ultrasonic sound wave to travel from one point to another is used to determine the speed of water. The Doppler ultrasonic flow meter measures changes in the frequency of a sound wave when it is reflected back from the moving object or moving water in this particular case.

So, these are the different types of meters that are used in pipelines or water supply pipelines. Meters are required for determining many things such as water consumption of the different socio-economic groups and the reason for the same. This can be then utilized to determine charges, requirement of cross-subsidy and so on.

(Refer Slide Time: 27:13)

Telemetry and SCADA systems

Telemetry enables collection of data:
Using sensors for level (in reservoir), pressure, flow, water quality (pH, turbidity, residual chlorines), data on the operation of pumps (voltage, amperes, energy consumed, operation and down times) at remote areas and then transferring the data via radio, telephone, VSAT, GSM / GPRS for review and decision making.

Automatic Meter Reading (AMR)

- Using smart meters water use data can be collected at regular intervals and can be read remotely.
- Readings by walk-by or drive-by method or through one-way or two-way communication with the utility.

Advanced Metering Infrastructure (AMI)

- Using smart meters with capacity for two-way communication between the meter and utility and between the meter and consumer.
- Meter can also receive (and often act on) instructions sent from the utility or consumer.

SCADA Systems

Telemetry and SCADA systems

Smart meters are the ones where we can collect automatic meter readings and at the same time, it would be able to transfer the data from that meter to outside. Or it could be two-way communication as well, in between the meter and the consumer, or the meter and the utility and so on.

Telemetry refers to the collection of data using sensors employed not only in the pipeline but also in water treatment plants, service reservoirs and so on. We put sensors in the water levels to understand the water levels in the reservoir. It is used to determine pressure, flow, water

quality, pressure and flow in pipelines, inside a water treatment plant, water quality inside pipelines in terms of its pH, turbidity, residual chlorine and so on.

It also collects data on the operation of pump such as voltage and ampere requirement, energy consumption, operation and downtimes for pumps based on which we can improve the efficiency of utilization of the pumps. And once all this data is being sensed then this data needs to be transmitted, and in case of remotes areas where people are not stationed like automatic pumping stations and automatic treatment units, then the data is transferred either via radio, telephone, VSAT, GSM, GPRS and different kind of IOT systems. This data is transferred to the headquarters for review and decision making. So, this is where the data is stored in a database and then it is analyzed to determine the trends, kind of leakages and so on. We can thus determine the water use data from meter at certain intervals or we can remotely read it.

Besides, we do not need to dig up a particular pipeline or if it is inside a particular of chamber, we do not need to open it up. We can just pass by and have a handheld device and there could be two-way communication between this device and the meter and the data could be downloaded from that particular meter. So, this is the automatic meter reading system.

And similarly, we have advanced metering infrastructure, AMI, where two-way communication is possible between the smart meter and the utility or between the meter and the consumer. That means, a consumer can give an input to that particular meter such as stop the connection, stop the flow, or hold the flow for say two months because he would be out of the house and or for the utility to let you know about change in a certain rate or some other instructions. This be done via two-way communication between the meter as well as the utility and the consumer. So, that is what advanced metering infrastructure is all about. So, AMR and AMI systems are gradually being deployed everywhere.

(Refer Slide Time: 31:06)

Telemetry and SCADA systems

SCADA Systems

- Supervisory Control and Data Acquisition (SCADA)
- Computer-aided system that collects, stores, and analyses the data for different operation and maintenance(O&M) purposes.
- Efficient and dynamic analysis on water quantity or water quality.
- Enables automatic control of equipment.

Benefits

- Daily, weekly, monthly, and or annual reports or schedules.
- Monitoring of inventories on spare parts.
- Seasonal changes and emergencies can be programmed.
- Consumption patterns linked to the weather conditions,
- Electrical energy consumption linked to consumer demand
- Record on system leaks, pump failures, etc.

Ahmedabad Municipal Corporation SCADA system
Monitoring of water quantity, quality and energy parameters of 148 water distribution centers, 4 french wells and 4 water treatment plants.
Rs 6 crore savings as electricity bill
Savings of 23 MLD water

[Source: <https://india.smartcitiescouncil.com/article/see-how-scada-system-helps-ahmedabad-water-dept-save-rs-6-cr-electricity-bill>]

Then we have the SCADA system. SCADA refers to supervisory control and data acquisition. It is a system where all the data that we are collecting from the sensors are stored and this data is analyzed so that we can streamline our operation and make it more efficient. We can carry out lot of analysis on the water quantity, water quality, the trends and accordingly we can adjust our operation which reduces the cost of operation. It through this kind of system we can automate the control of equipment as well. So, similar to communicating with this meter, we can also communicate with pump equipment and other things which are also present in the system.

So, the benefits of a SCADA system are multifold. We get reports out of this system which helps in the process of decision making, helps understand what kind of inventories we hold or require, what kind of expected failures or what parts should be replaced. We get to know about the different kind of seasonal changes and emergencies and what to do in those cases, what kind of systems to run which could then be programmed. Consumption patterns linked to weather conditions like rainfall, and accordingly we can adjust treatment rates and so on. Electricity energy consumptions, system leaks and pumps failures can also be monitored.

Gradually many municipalities in India are now installing this kind of SCADA systems and advanced meter systems. In Ahmadabad municipal corporation, they have installed the SCADA system, and they monitor water quantity, quality, and energy parameters in 148 water distribution centers, in 4 French wells and 4 water treatment plants. They have more or less automated the entire process by gathering data from all the different processes and they were able to save around 6 crore rupees as electricity bill and also 23 MLD of water by reducing wastage. The benefits definitely outweigh the complications for its installation costs and usage including training of staff.

(Refer Slide Time: 33:51)

Conclusion

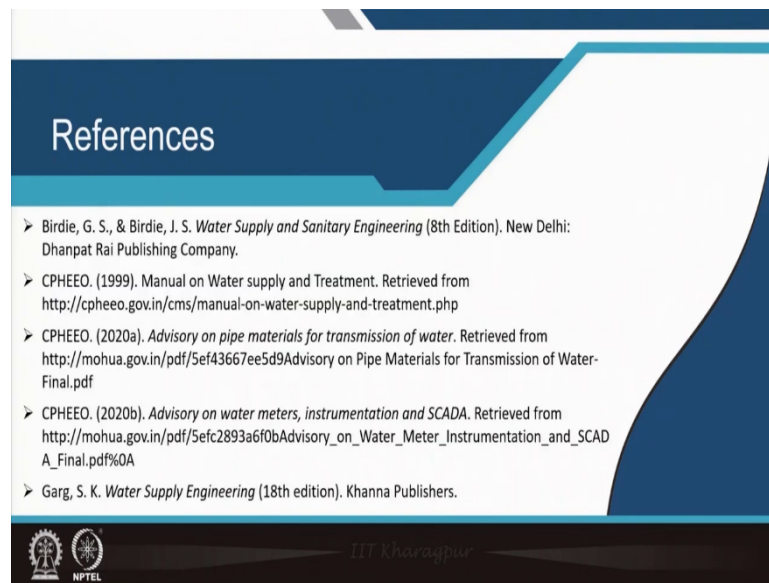

Selection of pipe material depends on several criteria and has to be undertaken considering the huge cost implications.
Metering and tariff policy is intrinsically linked.
AMR, AMI and SCADA systems are gradually introduced in various water supply utilities which are increasing efficiency in operation and maintenance and also reducing cost.

IIT Kharagpur
NPTEL

Conclusion

So, to conclude selection of pipe materials depend on several criteria, and has to be undertaken considering the huge cost implications. Metering and tariff policy is intrinsically linked. So, meters are extremely important to be installed in water supply distribution network. AMR, AMI and SCADA systems are generally introduced in various water supply utilities which are increasing efficiency in operation and maintenance and also reducing cost.
