Institute of Thoracic Medicine, Chennai

Lecture – 18
Radiology in diagnosis of Tuberculosis
Session 03

Welcome to the next session; the Radiology in the diagnosis of Tuberculosis.

(Refer Slide Time: 00:18)

The slide features a blue header with the text "Plan of session" in yellow. Below the header is a list of topics. The first three items are in black, and the last two are in red. A video inset of Dr. A. Chitrakumar is positioned on the right side of the slide. On the left side, there is a vertical blue bar containing the text "Manage TB" and "ICMR - National Institute for Research in Tuberculosis (NIRT) www.nirt.res.in" along with the ICMR logo.

- Interpretation of Normal chest x-ray
- Primary Pulmonary Tuberculosis
- Post primary Pulmonary Tuberculosis
- **Pulmonary TB in co-morbidities**
- **Pulmonary TB sequelae**
- Extra-Pulmonary TB

Next we will discuss the radiological features in a pulmonary TB in co-morbidities, I will pulmonary TB sequelae.

(Refer Slide Time: 00:31)

	Early HIV (CD4>200)	Advanced HIV (CD4<200)
Pattern	“Typical” (Post-primary)	“Atypical” (Primary)
Infiltrate	Upper lobes	Lower lobes, multiple sites, or miliary
Cavitation	Common	Less common
Adenopathy	Less common	Common
Effusion	Less common	More common

Vertical text on the left side of the slide: Manage TB, ICMR - National Institute for Research in Tuberculosis (NIRT), www.nirt.res.in

Tuberculosis is the most common opportunistic infection; affecting HIV seropositive patients and remains the most common cause of death in patients with HIV. HIV TB can occur in any stage of HIV, but the radiological pattern of TB in HIV depends on the immune status of the patient and CD 4 count. In a patient with early HIV where CD 4 count is more than 200 the radiological pattern usually occurs a typical post primary pattern.

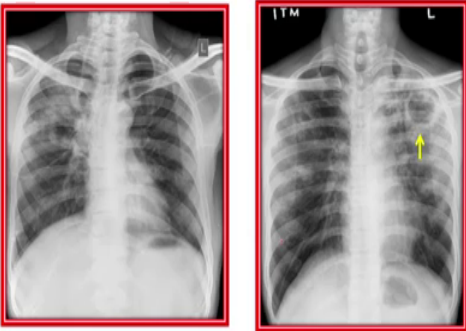

And the infiltrates are usually in the upper lobe typical and posterior segment; cavitation is more common, adenopathy and effusion are less common. In a patient with advanced HIV where CD 4 count is less than 200, that radiological features look like an atypical presentation of primary TB and infiltrates are seen more in the lower lobe and multiple sites and they may have a miliary pattern. Cavitation are less common in advanced HIV, but adenopathy and effusion are more common in advanced HIV.

Manage TB

Tuberculosis in HIV

High CD4 count

ICMR - National Institute for Research in Tuberculosis (NIRT)
www.nirt.res.in

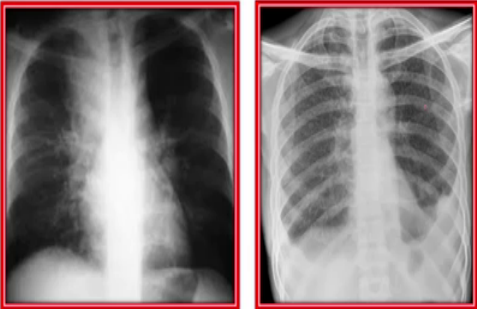

This X-ray showing tuberculosis in HIV where the CD 4 count are very high; so there is a classical of a consolidation it is a opacity involving the upper zone; that is typical and posterior segment typical of a post primary and there is also a cavity in the upper lobe.

(Refer Slide Time: 02:36)

Manage TB

Tuberculosis in HIV

Low CD4 count

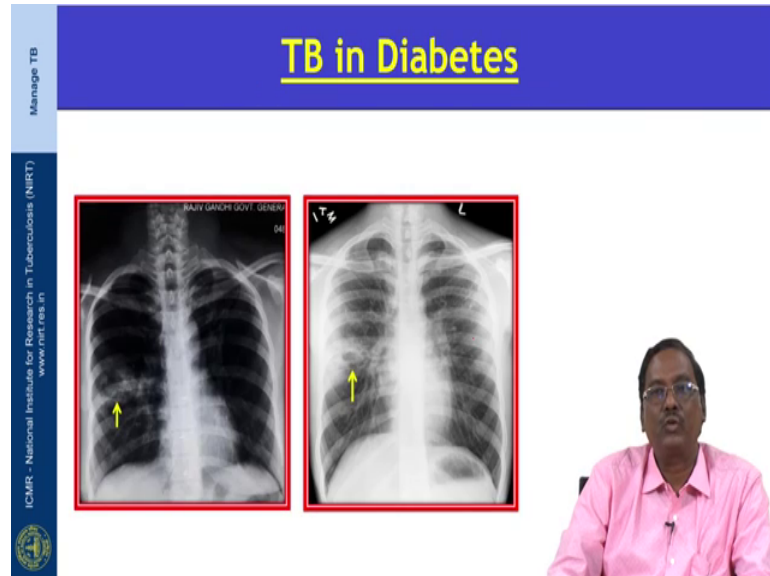

ICMR - National Institute for Research in Tuberculosis (NIRT)
www.nirt.res.in

Here there is a tuberculosis in HIV where the CD 4 count are very low this is a X-ray showing right paratracheal adenopathy; it is a similarly of a primary tuberculosis and

here there is a bilateral proliferation and also adenopathy. So, a typical of a radiological feature of a HIV TB in a low HIV of a low CD 4 count.

(Refer Slide Time: 03:10)

This X-ray shows tuberculosis in diabetes; diabetes estimated to be cause 15 percent of person tuberculosis cases. Patients with a diabetes have four fold increase risk of developing TB there is increased risk of failure, a relapse or delayed sputum conversion. The radiological presentation of tuberculosis in diabetes usually involve a lower lung field; the patterns are different the most important they have cavitation. So, 80 percent of the cases have a cavitation in a lower lung field and there will be nodule in 86 percent and accelerative relation in 22 percent.

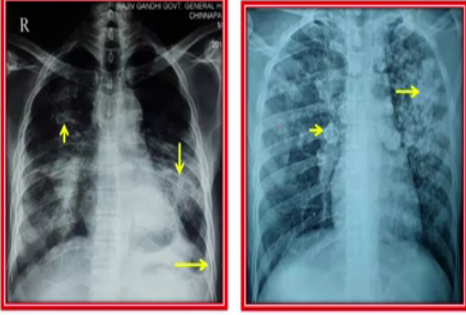

So, this is also a lower zone consolidation with the cavity this typical of a TB in diabetes.

(Refer Slide Time: 04:10)

Manage TB

TB in Silicosis

ICMR - National Institute for Research in Tuberculosis (NIRT)
www.nirt.res.in

ICMR - National Institute for Research in Tuberculosis (NIRT)
www.nirt.res.in

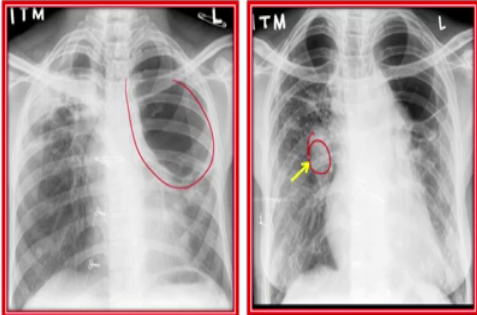

Tuber tuberculosis in silicosis tuberculosis is 3 to 7 times higher in persons with silicosis; radiological diagnosis of TB in silicosis is very difficult because, silicosis itself there will be a nodules and masses the radiological sign of TB in silicosis or when there is a rapidly developing soft (Refer Time: 04:41) nodule or conglomerate mass nodule.

A rapid changes in the radiological picture or presence of cavity in the nodule or opacity surrounding a pre existing nodule or development of pleural effusion and development of any middle lobe collapse because due to bronchial silicosis all these things we can suspect tuberculosis in a silicosis.

(Refer Slide Time: 05:12)

Manage TB

PT- Sequelae

ICMR - National Institute for Research in Tuberculosis (NIRT)
www.nirt.res.in

Destroyed Lung

So, coming to PT-sequelae; so sequelae can occur in both primary and post primary tuberculosis up to 40 percent of the patient with post primary they have a marked fibrotic response which manifest as a atelectasis, retraction of the hilum, mediastinal shift to the fibrotic side and compensatory emphysema.

So, what is destroyed lung? So, destroyed lung when will it defined destroyed lung when more than two-third of the lung tissue has been replaced by the cavity or fibrosis we call it as a destroyed lung. There is a complete destruction of the whole lung are major of part of the lung.

So, it is occur in a primary progressive primary TB and also post primary TB because of secondary infections. So, it is a X-ray showing a large cavity so destroyed lung. So, here is a destroyed lung, here there is a hilar enlargement; it is nothing, but this is a dilated pulmonary artery.

(Refer Slide Time: 06:33)

Manage TB

Broncho Pleural Fistula

ICMR - National Institute for Research in Tuberculosis (NIRT)
www.nirt.res.in

It is because of sequelae of TB because the patient is going for cor pulmonale. So, broncho pleural fistula it is due to establishment of spontaneous communication between bronchial tree and pleural space. The diagnosis is based on increasing amount of sputum production, multiple air cavity with air fluid level and shift of the mediastinum to the same side.

CT can demonstrate site of the communication between the pleural space and a air way. So, here there is a multiple cavity with a fluid level, the shift of the mediastinum to the opposite side. It is the sequelae occurring in a post primary TB.

(Refer Slide Time: 07:15)

Manage TB

Bronchiectasis

ICMR - National Institute for Research in Tuberculosis (NIRT)
www.nirt.res.in

Bronchiectasis is a common sequelae of tuberculosis; it is seen in both primary and post primary tuberculosis. It is present in 71 percent to 86 percent of the patients with an inactive disease; this is also sometimes seen in an active disease also 30 percent.

The bronchiectasis in TB is due to tuberculous bronchitis or this is due to fibrosis with subsequent fibrosis or destruction of the lung parenchyma with a traction bronchiectasis. This X-ray shows an upper lobe bronchiectasis; it is usually seen in pulmonary tuberculosis, it is a lower lobe see cystic bronchiectasis; here it is a cylindrical bronchiectasis.

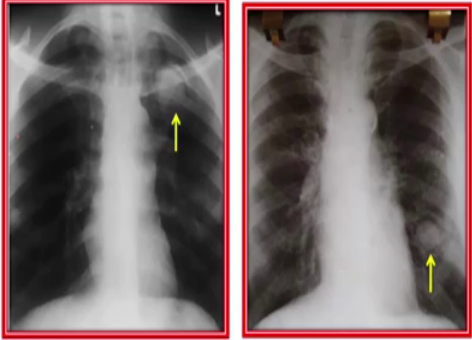

These are all as usual seen in a primary TB, here it is a post primary TB presenting with the bronchiectasis of the upper lobe.

(Refer Slide Time: 08:24)

Manage TB

Aspergilloma

ICMR - National Institute for Research in Tuberculosis (NIRT)
www.nirt.res.in

Aspergilloma it is seen in 11 percent of patients with a chronic cavitory disease. It is access for many years without any symptoms. Hemoptysis is the more commonest symptom and it is seen in 80 to 90 percent of the patient. Aspergilloma consists of a say mass of fungal hyphae and mixed with a mucus and a cellular debris.

So, radiologically it present as a mass in a pre existing cavity there is a presence of a air presents around the mass. So, we call it as a radiological sign we called as a monod sign.

So, here it is also a presence of a aspergilloma in a pre existing; cavity the complication is a hemoptysis.

(Refer Slide Time: 09:18)

Manage TB

Pleural thickening

ICMR - National Institute for Research in Tuberculosis (NIRT)
www.nirt.res.in

ICMR - National Institute for Research in Tuberculosis (NIRT)
www.nirt.res.in

Next is a pleural thickening. So, in a pleural effusion due to post primary TB; the pleural effusions are infected. So, it present as a loculated effusion and there is a delay in healing, they form more of a pleural thickening or calcification.

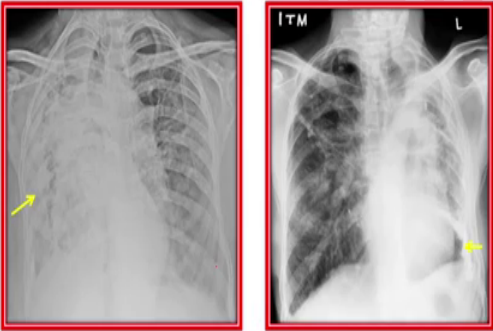

So, pleural thickening is seen in the visceral pleural layer. So, in a tuberculosis thickening is seen in a visceral pleural air, parietal pleura is rarely involved.

(Refer Slide Time: 09:57)

Manage TB

Fibrothorax

ICMR - National Institute for Research in Tuberculosis (NIRT)
www.nirt.res.in

ICMR - National Institute for Research in Tuberculosis (NIRT)
www.nirt.res.in

So, this X-ray showing a fibrothorax; it is the most severe form of a pleural fibrosis there is a extensive damage to the visceral pleura; the visceral pleura is completely thicken and there is the fusion of both visceral and a parietal pleura, obliterating the pleural space.

The mediastinum is shifted to the same side; there is a marked volume loss and the affected hemithorax and the also reduce to mobility of the lung. So, this is also a fibrothorax; there is the thickening of the both visceral and a parietal pleura.

(Refer Slide Time: 10:40)

Then this all the various parenchymal calcifications so it is a dystrophic calcification occurring in the damaged lung following a TB infection. This is a local organized process with local deposition of the crystalline hydroxyapatite calcium salt. So, this are all the calcifications. So, we can see them multiple parenchymal calcification.

So, with this we conclude the radiological features in a TB co morbidities and PT-sequelae.

Thank you.
